

How High-Profile Violence Against LGBTQ+ People Motivates Prosocial Attitudes Toward LGBTQ+ Group Members

July 26, 2023

Abstract

Does indirect exposure to civilian violence against LGBTQ+ people engender prosocial attitudes toward LGBTQ+ community segments among the mass public? Violence against LGBTQ+ people may reflect heteronormative societal values. Thus, these values may be resistant to introspection after high-profile violence against LGBTQ+ people. However, psychological insights suggest indirect exposure to violence against marginalized groups may motivate pro-LGBTQ+ beliefs. We adjudicate between these perspectives by evaluating if two prominent U.S. instances of violence against LGBTQ+ community members motivated prosocial beliefs toward LGBTQ+ community segments. Across three studies, we find indirect exposure to civilian violence against LGBTQ+ people increases support for the political rights of LGBTQ+ community segments and reduces negative attitudes toward LGBTQ+ group members. However, we find the adoption of prosocial attitudes is short-term. Our findings suggest unexpected and salient civilian violence against marginalized groups may not sustainably motivate prosocial beliefs toward targeted groups among the mass public.

Keywords: exposure to violence; political violence; prosocial attitudes; intergroup relations; LGBTQ+ politics

1 Introduction

Since the 1969 Stonewall Uprising, there have been numerous instances of anti-LGBTQ+ violence in the US. Violence against LGBTQ+ people may be conducted on the basis LGBTQ+ people violate heteronormative,¹ patriarchal, sexual and gender norms (Ott and Aoki, 2002). Despite some attitudinal and policy progress on LGBTQ+ rights (Flores, 2014), anti-LGBTQ+ violence and hate crimes have increased recently² while several states have introduced a record number of laws restricting LGBTQ+ rights in the last year.³ Perhaps the most prominent instance of recent perceptibly anti-LGBTQ+ violence was the 2016 Pulse massacre, where a gunman killed 49 clubgoers at an Orlando LGBTQ+ nightclub. These prominent violent acts, while sympathy-inducing within media and amongst political elites, are also reflective of heteronormative societal norms resistant to change. Therefore, an open question is whether *indirect* (i.e. observation of violence through media, word of mouth) exposure to prominent violence against LGBTQ+ group members perpetrated by civilians serves as an introspective moment among the mass public, shifting their attitudes in a prosocial manner toward LGBTQ+ community segments.

Although the mass public may have limited capacity to empathize with marginalized minority groups (Cikara et al., 2011), violence against marginalized groups may elicit prosocial attitudes among the mass public if the event is perceived as salient and illegitimate (Birkland, 1998; Branscombe and Miron, 2004; Harth et al., 2008). Thus, we hypothesize indirect exposure to sympathetic media coverage concerning prominent instances of civilian violence against LGBTQ+ people will elicit prosocial attitudes toward LGBTQ+ community segments among the mass public (Iyengar, 1994; Vossen et al., 2017). However, the adoption of prosocial attitudes toward marginalized groups may be short-term. Social group attitudes are typically durable, even in light of salient “focusing” events (Sears, 1993; Sigel-

¹ Heteronormativity is “the presumption and privileging of gender conformity, heterosexuality, and nuclear families over all other “deviant” forms of gender expression, sexuality, and families (Pollitt et al., 2021)”

²<https://www.hrc.org/press-releases/new-fbi-hate-crimes-report-shows-increases-in-anti-lgbtq-attacks>

³<https://www.aclu.org/press-releases/over-120-bills-restricting-lgbtq-rights-introduced-nationwide-2023-so-far>

man et al., 1997; Tuch and Weitzer, 1997; Kite et al., 2019). Moreover, immediate adoption of prosocial beliefs toward LGBTQ+ community segments after a violent event may be counterbalanced by countervailing information in a heteronormative society (Vuletic and Payne, 2019). Pro-LGBTQ+ elite messaging and pressure to support LGBTQ+ may also dissipate after an event loses salience (Downs, 1972), undercutting temporally sustainable prosocial attitudinal shifts (Zaller et al., 1992; Birkland and Lawrence, 2009).

We find theoretically consistent evidence across three studies evaluating the effect of two prominent instances of civilian violence against LGBTQ+ group members on mass attitudes toward LGBTQ+ community segments and their political rights: the 2016 Pulse massacre (Studies 1, 2) and Matthew Shepard's 1998 murder (Study 3). Study 1 uses a representative survey in the field during the massacre and an unexpected-event-during-survey-design (UESD) to assess if respondents interviewed after the massacre were more likely to support same-sex marriage. Study 2 uses an opt-in internet survey during 2016 and another UESD to assess if respondents taking the survey after Pulse hold weaker anti-gay attitudes. Study 3 uses several historical surveys to assess if Shepard's murder decreased the belief homosexuality is "morally wrong." Across all studies, we find the mass public adopts prosocial attitudes toward LGBTQ+ community segments and their political rights shortly after violence against LGBTQ+ group members. However, further tests demonstrate the effect of these incidents on prosocial beliefs *does not persist*.

Our theory and evidence makes several contributions. Our analysis is the first to examine the attitudinal consequences of real-world *civilian* violence against *LGBTQ+ community segments* on prosocial attitudes toward LGBTQ+ people among the *broader mass public*.⁴ Prior research on how indirect exposure to violence against marginalized groups may motivate prosocial attitudes in the US typically focuses on state (i.e. police) violence against Black people (Tuch and Weitzer, 1997; Sigelman et al., 1997; Reny and Newman, 2021). Extending research on the attitudinal consequences of violence to the domain of civilian vi-

⁴Some research examines how anti-LGBTQ+ violence motivates prosociality *among LGBTQ+ people* (Page, 2018).

olence against LGBTQ+ community segments is theoretically important since the prospect of prosocial attitudinal shifts toward victimized groups may be conditional on a) whether the violence is imposed by the state and b) the social group implicated by the violence.

One perspective is that the effects of *civilian* violence against LGBTQ+ group members on prosocial attitudes toward LGBTQ+ people may be *weaker* and *less temporally sustainable* than prior studies examining racialized *state* violence. The mass public may attribute *state* violence to systemic problems within reformable institutions, motivating mass preferences for policies benefiting targeted groups (Oskooii, 2016). Civilian violence may be rationalized as a problem inherent to a troubled individual as opposed to the aggregate queerphobic attitudes of the mass public (Ott and Aoki, 2002),⁵ undercutting introspection over one's own queerphobic attitudes. Moreover, unlike racialized state violence, the instances of violence we examine are not associated with subsequent mass social protest, which may sustain the violent event's salience and therefore facilitate temporally durable attitudinal shifts (Reny and Newman, 2021).

Another perspective is that the effects of violence against LGBTQ+ community segments on prosocial attitudes toward LGBTQ+ people may be *stronger* and *temporally sustainable* relative to prior studies examining the attitudinal consequences of racialized state violence. Racial attitudes tend to be relatively stable (Yadon and Piston, 2019),⁶ and preexisting evidence shows that prosocial attitudinal responses among the mass public to racialized state violence are temporally fickle (Tuch and Weitzer, 1997; Chudy and Jefferson, 2021; Nguyen et al., 2021). However, as far back as data could be recorded, the mass public has increasingly adopted prosocial attitudes toward LGBTQ+ community segments over time (Flores, 2014; Lewis et al., 2022). Therefore, the mass public may be inclined to engage in sustained introspection over their heteronormative, queerphobic attitudes in response to violence against LGBTQ+ individuals.

⁵ “Queer” denotes a sexual/gender identity that does not correspond to established ideas of sexuality and gender, especially heterosexual norms.

⁶But see Hopkins and Washington (2020)

Our evidence adjudicates between these perspectives and bolsters prior theory and evidence consistent with the attitudinal consequences of racialized state violence. Even in a distinct domain like civilian violence against LGBTQ+ people, the mass public may adopt prosocial attitudes toward targeted marginalized groups in the short-term, but these attitudinal shifts are unsustainable.

Our analysis also contributes to the broader *focusing event* literature (Birkland, 1998; Birkland, 1997). In the context of US violence, prior research demonstrates highly salient events, like mass shootings and racialized state violence, can shift mass attitudes, but perhaps only briefly since these events lose salience and are subject to countervailing information (Sigelman et al., 1997; Birkland and Lawrence, 2009). Additionally, preexisting LGBTQ+ politics research demonstrates important court cases facilitating LGBTQ+ rights (e.g. *Obergefell v. Hodges*) (Flores, 2014; Tankard and Paluck, 2017), Pride parades (Ayoub et al., 2021), and celebrities coming out (Miller et al., 2020), can motivate prosocial attitudes toward LGBTQ+ people. But, this research places little emphasis on the temporal sustainability of attitudinal shifts and does not focus on the consequences of violence against LGBTQ+ people on mass attitudes, which may *reflect*, instead of *undercut* queerphobic beliefs. We provide new evidence that bolsters prior findings on brief attitudinal shifts in response to salient “focusing events” in a previously unexplored domain across multiple studies.

Understanding the adoption of prosocial beliefs concerning marginalized groups after violent events, and the sustainability of adopted prosocial beliefs, is important in light of several prominent instances of civilian violence against marginalized groups in the US. These include James Byrd’s 1996 murder, a Black man lynched by white supremacists in Texas; the 2015 Charleston Church massacre, where a white supremacist murdered 9 churchgoers at a Black church; the 2015 Stanford Sexual Assault Case (*People v. Turner*), where a Stanford undergraduate man sexually assaulted a woman; the 2019 El Paso massacre, where a white supremacist killed 23 people and targeted Latinos on the basis of concerns over a “Hispanic

invasion of Texas”; the 2021 Atlanta spa shooting, where 8 people, mostly Asian women, were killed; the 2022 Buffalo massacre, where a white supremacist killed 10 black people because he thought non-white people were “replacing” white people; and the recent 2022 Club Q shooting, where 5 people were killed by a mass shooter at a Colorado Springs LGBTQ+ nightclub. A critical contribution inherent to our findings is that we show these high-profile violent events may not serve as temporally sustainable moments of reevaluation concerning the socio-political status of marginalized groups. Thus, our findings help explain why these events have not led to societal adjustment of beliefs perpetuating social inequalities.

2 Violence Exposure and Prosocial Attitudes

Preexisting theory and evidence demonstrate *direct* (i.e. directly experiencing violence) or *proximal* (i.e. having close social ties, like family, friends, or people you know, experience violence) exposure to violence during inter-group conflict may motivate parochialism, encourage intra-group but not inter-group altruism, and undercut the development of emotional substrates ensuring inter-group prosocial behaviors and attitudes, including (but not limited to), positive evaluations of outgroups and support for their political rights (Rusch, 2014; Lupu and Peisakhin, 2017; Mironova and Whitt, 2018; Hadzic et al., 2020). Other evidence, building on *post-traumatic growth* and *altruism born of suffering* theory (Staub and Vollhardt, 2010), demonstrates intergroup violence can motivate prosocial, altruistic attitudes and behaviors toward outgroups (Bakke et al., 2009). Some evidence suggests direct or proximal exposure to violence motivates inter-group prosociality since victimization generates a basis for empathy (Sirin et al., 2021). Although prior work suggests direct or proximal exposure to inter-group, mostly inter-ethnic, violence can motivate inter-group prosociality, it is less clear how one-sided⁷ *indirect* exposure to violence against LGBTQ+ people may influence prosocial attitudes toward LGBTQ+ group members among dominant group members or the mass public. In this context, we define prosocial attitudes as positive feelings toward

⁷“One-sided” violence refers to violence perpetrated by the dominant group.

LGBTQ+ group members and policies facilitating their rights or interests.

Indirect exposure to one-sided violence may not motivate prosocial beliefs. Insufficient media coverage and public attention to violent events may not produce agenda-setting effects that mobilize prosocial mass attitudes toward targeted groups (Birkland, 1998). Additionally, *Social Identity Theory* (SIT) implies dominant group members garner self-esteem from minority group marginalization (Tajfel and Turner, 1982). Thus, the mass public may garner psychic benefits from indirectly observing violence against minority groups (i.e. *schadenfreude*) (Cikara et al., 2014). Consistent with insights from *Inter-group Emotions Theory* (IET), these dynamics may be exacerbated by the absence of direct experiences with analogous violence that serves as a basis for empathy (Sirin et al., 2021). Moreover, the social distance between modal mass public members and, for example, LGBTQ+ people, may generate an empathy gap (Cikara et al., 2011), which, at least in the context of the Pulse massacre, may be amplified by the predominantly Latinx victims.

However, under some conditions, indirect exposure to one-sided violence against marginalized groups may motivate prosocial attitudes toward the group to ameliorate conditions concomitant with the violence. *Focusing event theory* implies violent incidents with high media salience can mobilize mass attitudes to support marginalized groups (Birkland, 1998), especially if elite and media messaging is framed sympathetically (Zaller et al., 1992; Iyengar, 1994). Consistent with *Dissonant Identity Priming* theory, sympathetic messages expressed by partisan elites in the aftermath of violence against marginalized groups like LGBTQ+ may motivate socially conservative co-partisans to rethink their prejudicial attitudes (Harrison and Michelson, 2017). The media also has a powerful influence on pro-LGBTQ+ mass attitudes. A cross-national study demonstrates positive LGBTQ+ media portrayals motivates support for LGBTQ+ rights (Ayoub and Garretson, 2017). Other studies demonstrate parasocial LGBTQ+ media contact reduces anti-LGBTQ+ prejudice and increases support for pro-LGBTQ+ policies (Miller et al., 2020). In sum, indirect exposure to *salient* and *sympathetic* messaging from media and elites after violence against LGBTQ+ group members

may encourage the adoption of prosocial attitudes toward LGBTQ+ community segments.

Moreover, other insights building on SIT and IET suggest dominant group or mass public members may feel one-sided civilian violence against marginalized groups (e.g. LGBTQ+) is illegitimate and reflects poorly on their stigmatizing beliefs (e.g. heteronormative, queerophobic attitudes), even if minority group marginalization otherwise facilitates self-esteem (Harth et al., 2008). Perceptions of illegitimacy may be magnified if the perpetrator is associated with perceptibly illegitimate groups (e.g. the Pulse massacre shooter, who pledged allegiance to the Islamic State, see Puar (2018)). Dominant group or mass public members may attempt to emotionally regulate these psychic costs by reacting to violence against marginalized groups with sympathy and/or empathy (Branscombe and Miron, 2004), motivating the downstream adoption of positive attitudes toward marginalized groups and policies ensuring their rights (Iyer et al., 2007). These theoretical propositions are consistent with evidence demonstrating empathetic feelings in response to observing LGBTQ+ discrimination elicit support for LGBTQ+ rights (Stotzer, 2009).

- **H1:** Indirect exposure to civilian violence against LGBTQ+ group members will motivate positive attitudes toward LGBTQ+ people and support for their political rights

Prior evidence corroborates the possibility of mass prosocial responses. Prior research demonstrates high-profile anti-Black police violence motivates pro-Black sentiment, acknowledgment of anti-Black discrimination, and police disapproval (Tuch and Weitzer, 1997; Sigelman et al., 1997; Reny and Newman, 2021; Nguyen et al., 2021).

3 Temporal Durability

Although indirect exposure to civilian violence against marginalized groups may motivate prosocial attitudes toward targeted groups, attitudinal shifts may not be sustainably long-term despite macro-level progressive shifts in LGBTQ+ attitudes (Flores, 2014). *Issue-attention cycle* theory posits the mass public may react to dramatic events highlighting

relatively ignored social issues, like violence against LGBTQ+ group members, in an initially proactive manner. However, attitudinal shifts that seek to resolve a social ill may not be sustainable when it becomes clear resolving the problem is difficult (e.g. reevaluating queerphobic beliefs offering a privileged social status) and the problem becomes less salient over time (Downs, 1972). Prior research implies sympathetic media and elite messaging after targeted violence needs to be persistent to generate sustainable prosocial beliefs (Zaller et al., 1992).

Moreover, prosocial attitudinal responses may not be genuine, but short-term impression management. Illegitimate violence rejected by society, media, and political elites may motivate prosocial expressions toward the targeted group among the masses to save face (Harth et al., 2008), but may not result in long-term attitudinal shifts motivated by the difficult task of dismantling hierarchical social relations (Nguyen et al., 2021). Short-term impression management may not be capable of undermining long-standing predispositions toward marginalized groups often rooted in pre-adult socialization (Sears, 1993; Kite et al., 2019). Long-term attitudinal shifts may also be undercut by countervailing pressure to adhere to queerphobic norms in an otherwise heteronormative society (Vuletich and Payne, 2019).

In addition, framing theory may help explain the potential absence of long-term prosocial attitudinal shifts. Story framing affects how the public assigns responsibility to an event in addition to preferred policy and societal outcomes (Kingdon, 1995). Media outlets may adopt episodic or thematic frames in their news coverage (Iyengar, 1994). Episodic frames emphasize event-centered information with attention toward an individual's actions (e.g. the perpetrator of violence against LGBTQ+ community segments) whereas thematic frames emphasize broader societal problems (e.g. queerphobia, heteronormativity). Ott and Aoki (2002) and Zahzah (2019) posit media frames of prominent instances of violence against LGBTQ+ people, such as the 1998 Matthew Shepard murder and the Pulse massacre, often emphasize the perpetrator's gratuitous violence instead of heteronormative and queerphobic undercurrents in U.S. society. These episodic frames may allow mass public members to

simply express prosocial attitudes toward LGBTQ+ to absolve oneself of guilt in the short-term but lose sight of reflecting over their potential quotidian role and participation in a queerphobic, heteronormative society in the long-term (Ott and Aoki, 2002; Nguyen et al., 2021). Moreover, at least in the context of the Pulse massacre (a mass shooting), conservative news outlets, like Fox News, may emphasize other issues, such as gun rights, that reduce sustained discussion of violence against LGBTQ+ group members that may motivate long-term prosocial belief adoption (Cassino, 2016).

- **H2:** Indirect exposure to civilian violence against LGBTQ+ community segments will not produce temporally sustainable prosocial attitudes toward LGBTQ+ people and their political rights

Preexisting evidence aligns with our hypothesis. Birkland and Lawrence (2009) demonstrate the Columbine shooting produced an immediate increase in gun control support, but the increase was not sustainable. Likewise, police evaluations declined immediately after the Rodney King beating, but rebounded in the long-run (Tuch and Weitzer, 1997). Moreover, BLM support increased after anti-Black murders and concomitant protests in 2020. But, support eventually declined to the pre-protest equilibrium (Chudy and Jefferson, 2021; Nguyen et al., 2021).

4 Context 1: The Pulse Nightclub Massacre

Studies 1-2 test **H1-H2** by evaluating the consequences of the Pulse nightclub massacre. The massacre was a terrorist attack and mass shooting that occurred on June 12, 2016 in Orlando, Florida. The massacre was perpetrated by Omar Mateen, a terrorist who pledged allegiance to ISIS. Mateen, armed with a semi-automatic rifle, killed 49 clubgoers and injured 53 others.⁸ After taking hostages, Mateen was killed by the police. The massacre was the deadliest incident of violence against LGBTQ+ people in U.S. history, deadliest U.S. terrorist

⁸<https://www.cnn.com/2016/06/12/us/orlando-shooter-omar-mateen/index.html>

attack since 9/11, and deadliest mass shooting until the 2017 Las Vegas shooting. During the massacre, Pulse was hosting “Latin Night.” 80% of victims were Latinx.

The nation reacted with sympathy after the massacre. Republican Florida Governor Rick Scott expressed support for those affected while instituting a state of emergency. The Obama administration expressed condolences and ordered the federal government to provide assistance in the investigation and to the community. In a press conference, Obama described the massacre as an “act of hate.” Many on social media, including 2016 presidential election candidates, congresspeople, political figures, foreign leaders, and celebrities expressed condolences to those affected.

The event was a highly salient “focusing event.” 90% of adults surveyed immediately after the massacre indicated they were closely following the incident (Figure A1). Media coverage of topics related to Pulse, LGBTQ issues, and terrorism discontinuously increased after the massacre (Figure A2). At the same time, Google searches related to the same topics peak the moment the massacre occurs (Figure A3). Importantly, media coverage and Google searches related to these topics were either declining or limited pre-massacre, suggesting anticipatory effects are unlikely to drive attitudinal shifts toward LGBTQ+ issues or people post-massacre. However, consistent with *issue-attention cycle* theory, media coverage and searches decline to their pre-incident levels by July, suggesting attitudinal responses to the massacre may be short-lived. Additionally, a Chicago Council on Global Affairs survey during the massacre (June 10-26) suggests the public was aware of the mass shooting since it expressed more concerns about terrorism and gun violence post-massacre (Figure A4).

The massacre was not simply interpreted as a terrorist attack, but targeted and illegitimate anti-LGBTQ+ violence.⁹ Consistent with Obama’s characterization of the massacre as an “act of hate,” the vast majority of the public understood the massacre as a anti-LGBTQ+

⁹Omar Mateen was not explicitly motivated by anti-LGBTQ attitudes. Mateen randomly targeted nightclubs to inflict mass casualties (see <https://www.nbcnews.com/feature/nbc-out/what-really-happened-night-pulse-n882571>). However, we do not believe Mateen’s motive matters for our interpretation of the results. Surveys suggest the mass public *perceived* the massacre as an anti-LGBTQ+ hate crime regardless of Mateen’s motive (Figure A5).

hate crime.¹⁰ In two polls, 85% and 70% of adults believed the shooting was an LGBTQ+ hate crime (Figure A5).¹¹

4.1 Study 1: TAPS

4.1.1 Data and Design

Study 1 uses The American Panel Survey (TAPS, Wave 55), to assess if exposure to violence against LGBTQ+ people motivates support for policies benefiting LGBTQ+ community segments. TAPS is a monthly online survey administered by the WashU-St. Louis Weidenbaum Center, with national probability sampling conducted by GfK/Knowledge Networks. TAPS includes post-stratification population weights.

The outcome is same-sex marriage support (*SSM support*). SSM is an important LGBTQ+ rights dimension and it implicates multiple LGBTQ+ community segments. Gay, lesbian, and bisexual people who want to marry a same-sex partner benefit from legalized same-sex marriage. Transgender people who have not changed their “legal” gender but seek to marry their partner in heterosexual romantic relationships, in addition to transgender people in same-gender relationships, would benefit from legalized same-sex marriage.¹² It is no surprise SSM approval is near-unanimous among LGBTQ+ people. 60% of LGBTQ+ people say SSM should be a priority even if it takes attention from other issues.¹³ TAPS asks respondents if they “generally support or oppose same-sex marriage,” with an option to indicate “no opinion.”¹⁴ We measure *SSM support* as a binary indicator equal to 1 if the respondent indicates they support SSM and 0 otherwise.

Our independent variable is being interviewed after the Pulse massacre (*post-Pulse*).

¹⁰The massacre’s victims spanned the LGBTQ+ spectrum, but gay men may have been centered in the media post-massacre (Ramirez et al., 2018). Although this might mean the massacre was not interpreted as violence against a broader LGBTQ+ community, this is not a shortcoming with our analysis, but with how society interprets violence against LGBTQ+.

¹¹See Appendix A.6 and A.10 for details on Figure A5 data.

¹²<https://transequality.org/issues/resources/marriage-equality-and-transgender-people>

¹³<https://www.pewresearch.org/social-trends/2013/06/13/a-survey-of-lgbt-americans/>

¹⁴See Section B.1 for outcome measurement details.

TAPS was fielded between 06/08/2016-07/08/2016. Pulse occurs on 06/12/2016, allowing us to implement an Unexpected Event During Survey Design (UESD) with TAPS comparing *SSM support* for respondents interviewed pre- and post-Pulse (Muñoz et al., 2020). *Post-Pulse* is a binary indicator equal to 1 if a respondent is interviewed after 06/12/2016, 6AM EST. Since we cannot be certain respondents perceived the massacre, the *post-Pulse* coefficient is interpreted as an “intent-to-treat” effect (ITT). However, Figures A1-A4 suggest the public was attentive to the massacre. Moreover, TAPS respondents are more likely to believe ISIS is an important issue *post-Pulse* (Figure B25), suggesting they “received the treatment” since the massacre’s perpetrator pledged fealty to ISIS. If we uncover support for **H1**, the *post-Pulse* coefficient would be *positive* if the outcome is *SSM support*.

Online survey respondent inattentiveness produces low quality responses that attenuate associations of interest (Read et al., 2021). Attention is critical for question comprehension and retrieval of relevant information from memory to form a judgement (Krosnick and Alwin, 1987). Our design depends upon respondents cognitively making connections between violence against marginalized groups they observe in mass media and their policy preferences implicating said groups. Prior research suggests very quick and very slow survey response times are associated with lower attention and quality responses (Malhotra, 2008; Read et al., 2021). In TAPS, the minimum response time was 3 minutes, insufficient to process a \sim 250 item survey. Furthermore, the maximum response time is 34,586 minutes, raising the possibility some respondents were multi-tasking, distracted, or intermittently engaging the survey with low effort. Thus, in the absence of internal attention checks, we truncate the sample to respondents who completed the survey in a “reasonable duration” of time, defined as those who took between 15-60 minutes to complete the survey. Our truncation is consistent with the rule of thumb by Roßmann (2010), who suggest removing respondents below 60% the median completion time.

The final TAPS data contain $N = 1142$ respondents, with 682 (60%) interviewed before Pulse and 460 after (40%). Truncation is unlikely to undercut generalizability. There are

limited differences between inattentive and attentive TAPS respondents (Figure B26, Panel A). Additionally, the truncated sample is compositionally similar to the full TAPS sample and the “gold standard” in election studies, the 2016 ANES (Figure B26, Panel B, Table B2). Although our truncation is arbitrary, the results are insensitive to using the initial raw data or alternative response time cut-offs for “reasonable duration (Figure B26, Panel C).”

Before we describe Study 1’s results, we demonstrate the *post-Pulse* coefficient is insulated from bias by validating UESD identification assumptions. The first assumption is ignorability. Treatment status should be independent of potential outcomes conditional on random sampling. Consequently, respondents interviewed before and after Pulse should be compositionally similar. Figure 1, Panel A supports the assumption. Respondents interviewed *post-Pulse* are compositionally similar to respondents interviewed pre-Pulse across 20 baseline covariates with the exception of age (see Section B.4 for more information on baseline covariate measurement), a finding consistent with multiple testing.

Excludability is another key UESD identification assumption: any difference between respondents interviewed before and after Pulse should be the sole consequence of the event. The “treatment” is not just the massacre, but also collateral media attention, much of which was sympathetic to the massacre’s victims. However, outside the massacre, there are no punctuated moments of media attention over LGBTQ+ issues or violence against LGBTQ+ people during the month TAPS was fielded (June, Figures A2 and A3), suggesting the absence of simultaneous events that could motivate pro-LGBTQ+ attitudes.

In addition, it is unlikely preexisting *SSM support* time trends are driving the result (Muñoz et al., 2020). We subset TAPS to the pre-Pulse period and assess the placebo “effect” of being interviewed after the median pre-treatment date and find null results (Table B4).

4.1.2 Results

Consistent with **H1**, respondents interviewed *post-Pulse* are 13 and 10 percentage points more likely to support SSM not adjusting and adjusting for covariates ($p < 0.01$, $p < 0.05$,

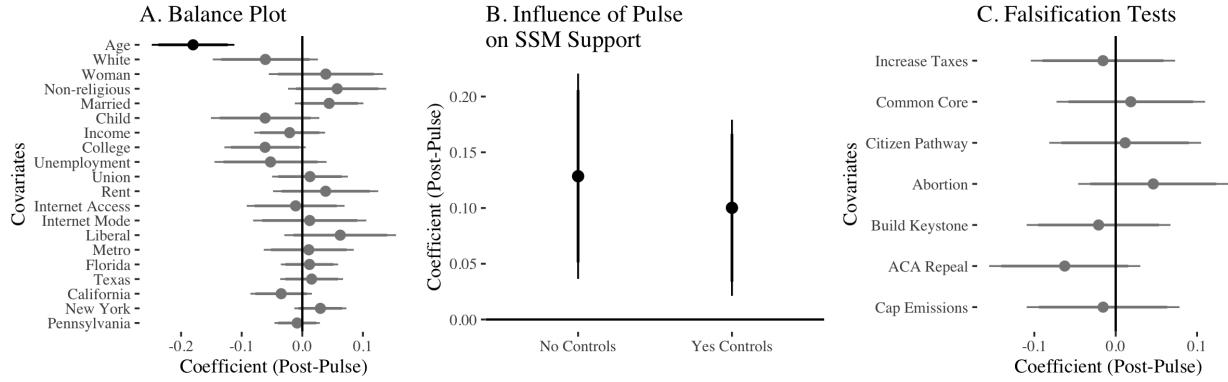

Figure 1: Same Sex Marriage Support Increases After Pulse. Panel A displays respondent covariate balance before and after Pulse. Panel B characterizes the *post-Pulse* ITT effect on *SSM support* with and without covariate adjustment. Panel C displays falsification tests characterizing the unadjusted ITT effect of *post-Pulse* on LGBTQ+-irrelevant policy outcomes. Black coefficients are statistically significant, grey otherwise. All estimates use population weights. All covariates scaled between 0-1. 95% CIs displayed from HC2 robust SEs. See Tables B5, B6, and B7 for regression tables characterizing the reported coefficients in this figure.

see Figure 1, Panel B). These coefficients are 20-26% of the outcome standard deviation.

Our results are robust. Our findings are likely not driven by secular dynamics outside the massacre. Falsification tests on treatment-irrelevant outcomes such as support for increasing taxes, common core, a citizenship pathway, abortion, the Keystone pipeline, ACA repeal and emission caps are statistically null (Figure 1, Panel C). These falsification tests suggest the chance imbalance on age does not implicate balance on policy preferences.¹⁵ The results are not driven by outcome item non-response since non-response is balanced for pre- and post-Pulse respondents (Table B3). The results are not driven by seasonal trends, the influence of Pulse is unique to 2016. Leveraging 3 surveys fielded in June 2012, 2013, and 2017, we show the influence of being interviewed after the massacre's calendar day on *SSM support* is null (Figure B29), suggesting there are no secular dynamics intrinsic to the month of June that could explain our findings (e.g. Pride Month). Our findings are robust to small temporal bandwidths before and after the massacre less susceptible to secular temporal trends that could influence *SSM support* (Figure B30). Finally, given we are deriving intent-to-treat

¹⁵Imbalance on age may not induce bias in TAPS since age is unrelated to *SSM support*, so it does not explain *joint* treatment and outcome variation (Table B6).

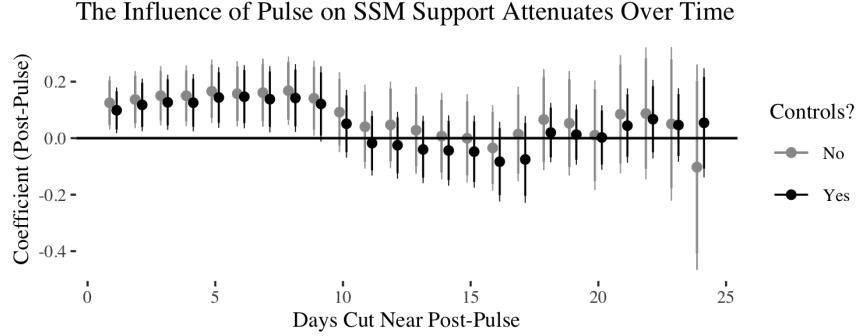

Figure 2: The Influence of Pulse on SSM Support Attenuates Over Time. X-axis is days cut from moment of Pulse massacre after the massacre (with days after intact). Y-axis is the *post-Pulse* coefficient. 95% CIs from robust SEs. See Table B8 for regression table characterizing reported coefficients in this figure. See Section B.8.5 for control covariate coefficients.

post-Pulse coefficients, we test if the influence of *post-Pulse* is heterogeneous by political interest or news consumption (Reny and Newman, 2021). We do not find the influence of *post-Pulse* is stronger for the politically interested and news consumers (Section B.14). However, this may not be cause for concern given 90% of the public was closely following the shooting (Figure A1), suggesting high treatment reception regardless of respondents' dispositional political interest or news consumption.

4.1.3 Temporal Persistence

We test **H2** by assessing if the influence of Pulse on *SSM support* is temporally durable. We remove observations in the days immediately *post-Pulse* but not after those days, and re-analyze the influence of being surveyed *post-Pulse*. The logic is that respondents interviewed immediately after Pulse may be the most susceptible to shifting attitudes toward LGBTQ+ community segments. Removing them may help us evaluate attitudinal decay by comparing respondents interviewed just before and some days after Pulse. After removing respondents interviewed between 1-10 days *post-Pulse*, the influence of being interviewed *post-Pulse* on *SSM support* is statistically null (Figure 2).¹⁶ In sum, consistent with **H2**, the massacre

¹⁶Only 1/20 covariates are imbalanced after cutting 2, 4, 6, 14, 16, 21, 22 days post-Pulse (Table B17), suggesting the results on Figure 2 are not driven by statistical imbalance.

motivated an increase in *SSM support*, but the increase was not temporally durable.

4.2 Study 2: PI S-IAT Data

4.2.1 Data and Design

Study 2 examines if the public adopts positive attitudes toward LGBTQ+ community segments *post-Pulse*. We use Project Implicit (PI) data on U.S. respondents who self-selected into and completed an internet survey in 2016 asking questions on their explicit attitudes toward gay people in addition to measuring their implicit anti-gay bias via PI's Sexuality Implicit Association Test (S-IAT, $N = 43,950$).¹⁷ On average, 175 U.S. respondents completed the PI S-IAT survey each day during 2016.¹⁸

The PI data are not population representative. The sample contains more youth (68% aged 18-29 vs. 18%), women (65% vs. 51%), liberals (57% vs. 41%), college educated (44% vs. 29%), and non-whites (36% vs. 22%) than TAPS. However, although the PI sample is disproportionately composed of respondent attributes associated with pro-LGBTQ+ attitudes, the empirical conclusions we draw from the PI sample may translate to a representative population. Prior research demonstrates non-representative internet samples respond similarly to external stimuli as representative samples (Coppock, 2019). If Study 2 corroborates results from a nationally representative sample (Study 1), we may have confidence Study 2's findings are generalizable.

The outcomes are the S-IAT *D-score*, *straight bias*, and *heterocentrism*. The S-IAT calculates normalized averages of how quickly respondents associate negative/positive attributes to gay/straight people relative to negative/positive attributes to straight/gay people in the form of a *D-score*. The *D-score* ranges from -2-2. Higher values suggest implicit bias against

¹⁷Data available here: <https://osf.io/yjqmw/>. See <https://implicit.harvard.edu/implicit/education.html> for Project Implicit information. See <https://implicit.harvard.edu/implicit/selectatest.html> to take the S-IAT.

¹⁸We exclude respondents interviewed after 09/08/2016 due to order effects since the S-IAT measurement changes from 188 to 200 trials by cutting a task block at that moment.

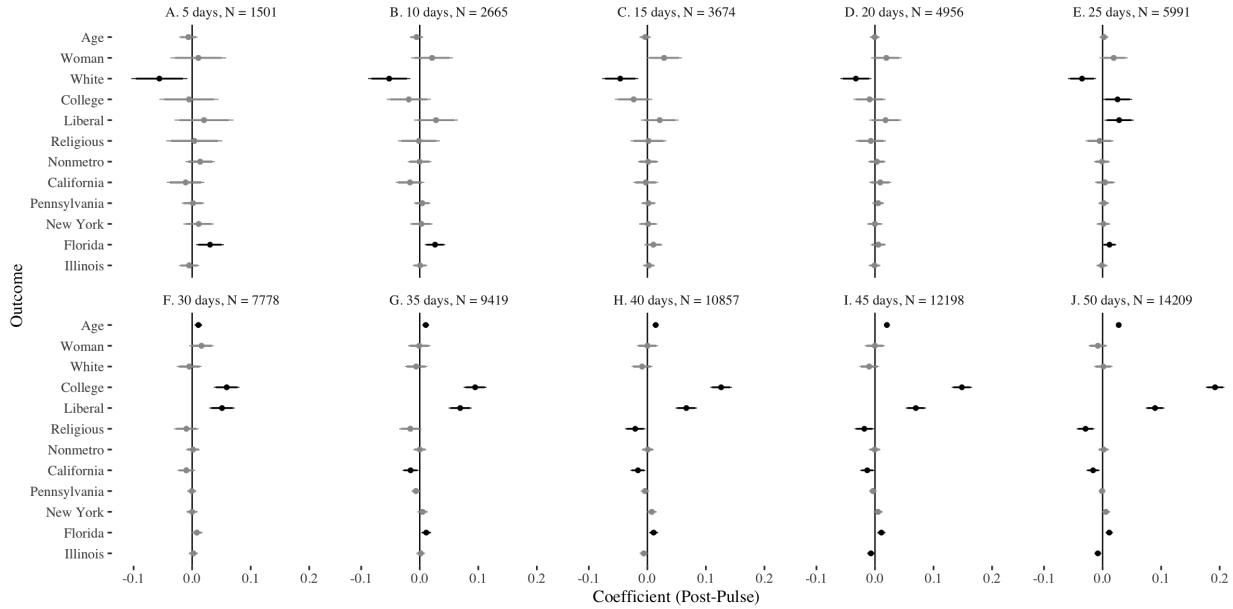

Figure 3: Balance on IAT Taker Composition Before and After the Massacre. Each panel characterizes covariate balance for different bandwidths (see plot title, with sample size). The x-axis is the *post-Pulse* coefficient derived from separate regression models regressing a baseline covariate (y-axis) on *post-Pulse*. Black coefficients are statistically significant, grey otherwise. See Section C.5.1 for regression tables characterizing these balance plots.

gay people (i.e. associating negative attributes to gay people) (Greenwald and Lai, 2020).¹⁹

Given the indirect measurement mechanism, the *D-score* may be less influenced by impression management to be perceived as pro-gay after the massacre (Greenwald and Lai, 2020). Although the IAT is not completely insulated from introspection, the modest-to-moderate correlation between the *D-score* and explicit bias measures suggests the IAT measures attitudes that are difficult to manipulate. The *D-score* is a well-established measure and associated with several objective covariates characterizing subordination vis-a-vis the relevant group (Ratliff and Smith, 2021).

Heterocentrism and *straight bias* are explicit anti-gay bias measures. *Heterocentrism* is the difference in 10 point feeling thermometers for straight and gay men. *Straight bias* is a 7 point measure from “I strongly prefer gay to straight people” to “I strongly prefer straight to gay people.” The *D-score*, *straight bias*, and *heterocentrism* are rescaled between 0-1.

¹⁹See Section C.2 for more *D-score* measurement details.

Although *heterocentrism* is explicitly about gay men, and *straight bias* is implicitly about gay men, the *D-score* does not just capture attitudes toward gay men, but also lesbians. In effect, the *D-score* implicates gay men, lesbians, and bisexual people (in addition to transgender people involved in same-gender relationships). Moreover, even if our outcomes in Study 2 are limited when it comes to measuring attitudes toward the broader LGBTQ+ community (e.g. transgender people), attitudes toward gay people are strongly correlated with attitudes toward transgender people (Norton and Herek, 2013), which may be pronounced given the Pulse massacre also affected transgender people.²⁰ Therefore, our Study 2 outcomes likely implicate large segments of the LGBTQ+ community. Given the outcomes characterize negative attitudes toward LGBTQ+ community segments, unlike Study 1, if **H1** is supported, the *post-Pulse* coefficients should be *negative*.

Study 2 is valuable because it allows us to assess additional outcomes characterizing support for LGBTQ+ community segments beyond the dimension of same-sex marriage and it is a replication of Study 1 using a different sample, hedging against the possibility Study 1 is a statistical fluke. Prosocial attitudes are multidimensional and not correlated 1-to-1 with each other. Therefore, demonstrating similar results across multiple studies with distinct outcomes (e.g. policy preferences *and* affective attitudes) suggests our theory and evidence may have broad applicability along several attitudinal dimensions. The *D-score* is particularly valuable since we can demonstrate prosocial attitudinal shifts, at least temporarily, may not be due to impression management.

Like Study 1, we use an Unexpected Event During Survey Design (UESD) with the PI S-IAT data to evaluate how anti-gay attitudes shifted *post-Pulse*. Given the large number of individuals taking the S-IAT per day, we estimate the influence of taking the S-IAT *post-Pulse* using respondents taking the PI S-IAT 5-50 days before and after the Pulse massacre in addition to the full 2016 sample between January-September.

We validate the ignorability UESD identification assumption, that is, “treatment” is

²⁰<https://www.advocate.com/crime/2016/6/17/pulse-survivor-stop-being-shady-and-messy-just-love-one-another-video>

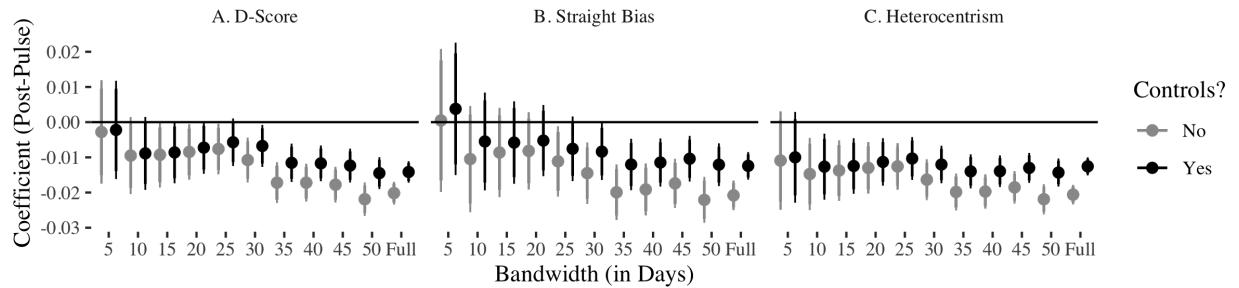

Figure 4: Influence of Pulse massacre on Anti-Gay Attitudes. The x-axis is the bandwidth (in days) used. The y-axis is the *post-Pulse* coefficient. All covariates rescaled between 0-1. 95% CIs displayed from robust SEs. See Sections C.5.2 and C.5.3 for corresponding regression tables.

independent of potential outcomes. Unlike Study 1, respondents are not randomly sampled, but self-select, into the PI S-IAT survey. Therefore, sample composition may be more likely to shift due to external events or secular temporal trends. We expect respondents surveyed shortly before and after the massacre will be compositionally similar. However, respondents may be increasingly dissimilar in samples that include respondents taking the survey well before or after the massacre. Figure 3 verifies our expectation. For samples with respondents who took the PI S-IAT 5-20 days (Panels A-D), there is statistical balance on respondent characteristics surveyed before and after Pulse on 1-2/12 baseline covariates. For samples with respondents who took the PI S-IAT 25-50 days, there is imbalance on 3-7 baseline covariates (Panels E-J). Given the 15 and 20-day bandwidth samples are only imbalanced on whether a respondent is white, we prioritize interpreting the influence of *post-Pulse* on anti-gay attitudes using these samples (yet display all bandwidth sample estimates between 25-50 days for transparency). These findings suggest our coefficient estimates, particularly for the 15 and 20-day bandwidth samples, are relatively insulated from omitted variable bias.

4.2.2 Results

Figure 4 displays *post-Pulse* intent-to-treat coefficients where the outcome is the daily *D-score*, *straight bias*, and *heterocentrism*. Honing in on 15 and 20-day sample bandwidth estimates, respondents surveyed *post-Pulse* have a lower *D-score* ($-0.01, p < 0.10$) and *het-*

erocentrism (-0.01, $p < 0.01$), equivalent to roughly 7% and 8% of the respective outcome standard deviations pre-Pulse. Although these coefficients are small, they are reasonable and likely underestimated (See Section C.4).

The massacre does not appear to statistically reduce *straight bias* except in sample bandwidths with higher covariate imbalance (e.g. 25-50 days). Given *straight bias* is a highly explicit measure, the absence of a statistically reliable shift in *straight bias post-Pulse* may be a function of impression management on part of respondents disposed against LGBTQ+ whose attitudes may otherwise shift in favor of LGBTQ+ through indirect bias measurement (Greenwald et al., 1998). In sum, we find support for **H1** that indirect exposure to violence against LGBTQ+ people motivates prosocial attitudes.

We conduct several robustness checks. We show preexisting time trends are not driving our results. We estimate the influence of taking the PI S-IAT 15 and 20 days pre-Pulse relative to 16-30 and 21-40 days pre-Pulse on the *D-score* and *heterocentrism*. We also estimate the influence of taking the PI S-IAT after (2016-03-07 to 2016-06-11) relative to before (2016-01-01 to 2016-03-06) the median pre-treatment date. These placebo estimates are statistically null, suggesting secular pro-gay time trends do not explain our findings (Figure C32).

We attempt to rule out if systematic temporal trends near June motivate prosocial attitudes toward gay people other than the massacre. Thus, we assess the influence of placebo estimates comparing *D-score* and *heterocentrism* 15 and 20 days before and after June 12, the Pulse massacre calendar day, during the years 2010-2015 and 2017-2018. We find no consistent influence of these placebo estimates on the *D-score* and *heterocentrism* (Figure C33).

We demonstrate our findings may not be due to a secular attitudinal trend in favor of marginalized groups through a series of falsification tests assessing if attitudes toward Black people, Asians, the differently-abled, Arabs, darker-skin people, and women shifts *post-*

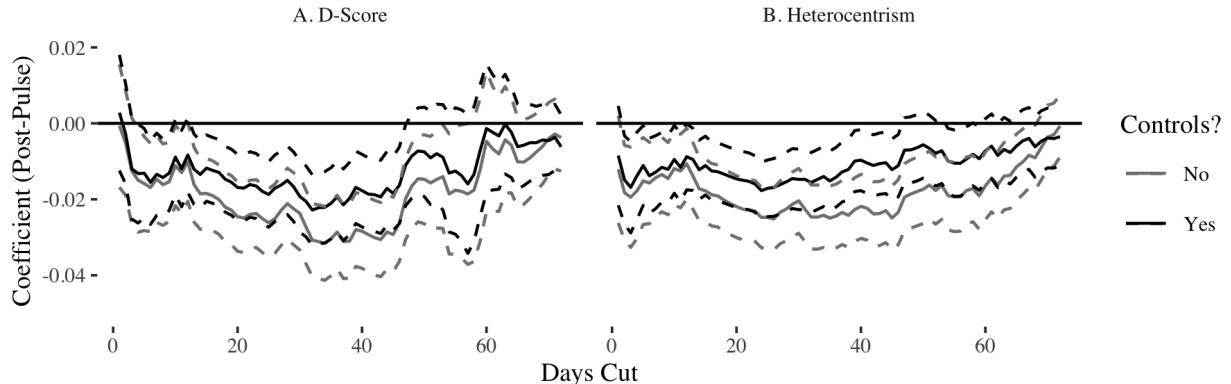

Figure 5: The Influence of Pulse on Reducing Anti-Gay Attitudes Attenuates Over Time. X-axis is days cut from moment of Pulse massacre after the massacre (with 15 days after kept intact). Y-axis is the *post-Pulse* coefficient. 95% CIs from robust SEs. See Tables C32, C33, C34, and C35 for tables characterizing the displayed coefficients. See Sections C.5.8 and C.5.9 for control covariate coefficients.

Pulse using the 15 and 20-day bandwidth samples.²¹ Across 28 statistical tests, only 3 are significant (Section C.8), suggesting our findings are not driven by secular liberal attitudinal trends toward marginalized groups.

Given respondents self-select into the PI S-IAT, we may be concerned systematic sorting induces bias (e.g. pro-gay people taking the survey *post-Pulse*). We do not believe sorting is a concern. If more pro-gay individuals were taking the survey *post-Pulse*, *post-Pulse* respondents would be younger, more liberal, less religious, and more college-educated in the samples of interest, but they are not (Figure 3, Panels C-D). Second, if sorting were operative, we may expect more respondents taking the PI S-IAT *post-Pulse*. We conduct a difference-in-means comparing the number of daily respondents *post-Pulse* relative to pre-Pulse, and do not statistically find more respondents took the PI S-IAT *post-Pulse* (Table C51).

²¹Falsification test data comes from separate Project Implicit surveys co-currently available to take in addition to the anti-gay attitude survey.

4.2.3 Temporal Persistence

We examine if the *D-score* and *heterocentrism* decrease is temporally sustainable. Consistent with **H2**, loess models fit on the daily mean *D-score* and *heterocentrism* over time in 2016 suggest anti-gay attitudes decreased *post-Pulse*, but rebounded to pre-Pulse levels around August (Figure C31). We conduct a formal test of the sustainability of attitudinal shifts *post-Pulse* and compare PI S-IAT respondents surveyed 15 days pre-Pulse to those surveyed 15 days after 1-72 days *post-Pulse* (leaving at least 15 days up to the end of the post-treatment sample in the 2016 PI S-IAT data). This exercise allows us to compare individuals surveyed prior to Pulse to those surveyed some time away from Pulse at multiple time intervals. Respondents in time intervals that cut more days *post-Pulse* are temporally further away from the massacre and potentially more subject to attitudinal decay in pro-gay beliefs. Figure 5 demonstrates the decrease in the *D-score* and *heterocentrism* was fairly sustainable, up to 40 days *post-Pulse*. However, after 40 days, the influence of *post-Pulse* attenuates toward 0 statistically and substantively.²² In sum, consistent with Study 1 and **H2**, Study 2 suggests the Pulse massacre motivated prosocial beliefs, but not durably.

4.3 Mitigating Bundled Treatment Concerns

One issue is that the Pulse massacre is a “bundled treatment.” It is also a terror attack and instance of violence against predominantly Latinx victims. Therefore, it is unclear if respondents adopted prosocial beliefs toward LGBTQ+ community segments because the massacre was a terror attack or anti-Latinx attack instead of an instance of perceptibly anti-LGBTQ+ violence. We mitigate these concerns with a series of tests and auxiliary evidence outlined in Section A.12. We are aware our tests do not entirely mitigate the bundled treatment problem since our results may be due to the *combination* of circumstances associated with the Pulse massacre. Therefore, we replicate the spirit of Studies 1 and 2 by

²²After cutting 40 days *post-Pulse*, there is covariate imbalance, but this does not invalidate Figure 5. After covariate adjustment, the *post-Pulse* coefficients are always attenuated toward zero, suggesting temporal attenuation occurred *earlier* than our results suggest (Section C.10).

assessing the influence of an instance of violence against an LGBTQ+ group member that was also *not* a terror attack nor an attack against predominantly non-white victims.

5 Context 2: Matthew Shepard's Murder

Although we provide evidence Studies 1-2 are internally valid, they may not be externally valid. The Pulse massacre is a highly unique instance of violence against LGBTQ+ people. It is the deadliest instance of violence against LGBTQ+, is the second deadliest mass shooting, has predominantly Latinx victims, was ISIS-inspired terrorism, and occurred after seminal gay rights victories (e.g. same-sex marriage). Therefore, it may be prudent to assess if a distinct instance of violence against LGBTQ+ group member(s) also motivates prosocial beliefs toward LGBTQ+ community segments. Consequently, we examine how the 1998 murder of Matthew Shepard, a white gay Wyoming college student, by two white men, influenced the public's beliefs toward homosexuality during a relatively more homophobic temporal context.

On October 6, 1998, Shepard was brutally beaten by Aaron McKinney and Russell Henderson. The incident was heavily covered by national media (Loffreda, 2001). Shepard died six days after the attack on October 12. The nation reacted with outrage and sympathy. A bipartisan group of Congresspeople condemned the murder and expressed condolences. A vigil was held outside the US capital on October 15, where thousands of people, including current and former Congresspeople and celebrities, gathered to pay their respects to Shepard. Advocates note Shepard's murder engendered a "seismic shift in attitudes towards the LGBTQ community."²³ Indeed, more than a decade after Shepard's murder, Congress passed the Matthew Shepard and James Byrd Hate Crimes Prevention Act, which expanded the power to prosecute sexuality-based hate crimes.

On the month of Shepard's murder, the number of gay-related news articles was 150%

²³<https://www.nbcnews.com/feature/nbc-out/two-decades-after-matthew-shepard-s-death-lgbtq-community-still-n919401>

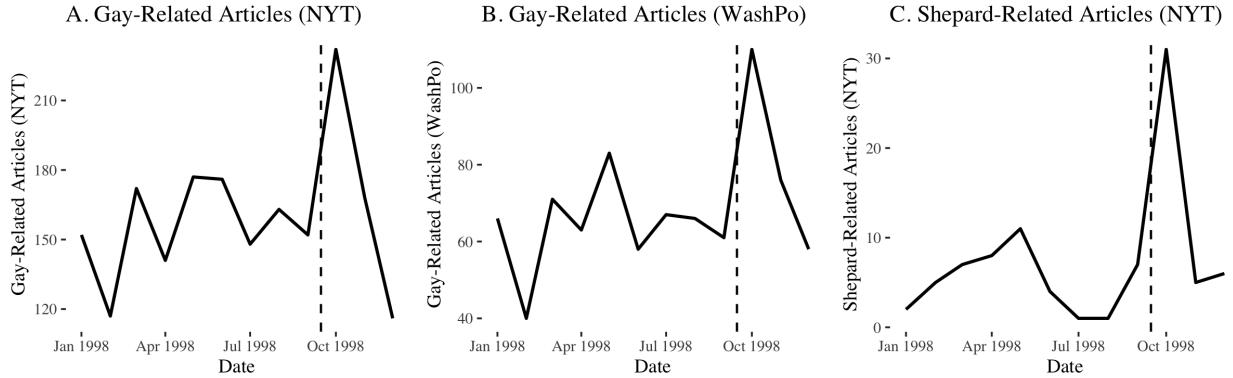

Figure 6: Media Coverage of Gay-Related Content in 1998. Panels A/B display the number of NYT/Washington Post gay-related articles (y-axis) by month (x-axis). Panel C displays the number of gay-related articles related to Shepard or anti-gay violence by month. Dashed vertical line denotes the period Shepard is murdered.

(NYT) and 172% (WashPo) of the Jan-Sep 1998 average (Figure 6).²⁴ Consistent with *issue-attention cycle* and *focusing event* theory, media attention to Shepard’s murder was immediately intense but quickly declined, suggesting attitudinal responses may be short-lived.

5.1 Study 3

5.1.1 Data and Design

To evaluate if exposure to Shepard’s murder decreased anti-gay attitudes, we identify surveys with similar items characterizing attitudes toward gay people shortly before and after Shepard’s murder.²⁵ We identify two nationally representative CNN telephone polls asking respondents if they believe homosexuality is “morally wrong” (*moral wrong*) 4 months before and 2 days after Shepard’s death (CNN Jun. 1998, $N = 1016$; CNN Oct. 1998, $N = 1036$).²⁶ We stack these datasets and identify overlapping control covariates from each survey.²⁷ We

²⁴See Appendix D.1 for details on media data.

²⁵We use the search terms “homosexuality” OR “homosexual” OR “gay” in Roper iPoll between 1996-2000 to identify gay-related items around Shepard’s murder.

²⁶We found two other items that could serve as potential candidates for assessing the influence of Shepard’s murder on attitudes toward LGBTQ+ group members, however, we do not use them for various reasons that we outline in Section D.4.

²⁷See Section D.2 for more details on sampling methodology for the two CNN polls.

then compare respondents interviewed after Shepard’s murder (*post-Shepard*) to those before to assess if anti-gay violence exposure decreased the belief homosexuality is morally wrong, consistent with **H1**. We focus on surveys with the *moral wrong* outcome for 3 reasons. First, it is asked on three surveys after Shepard’s murder (in 1998, 2001, 2004), allowing an assessment of long-term attitudinal shifts. Second, there are multiple pre-Shepard surveys with the same item, allowing us to conduct placebo tests to rule out if the *post-Shepard* effects we identify are a function of secular progressive attitudinal trends concerning the morality of homosexuality. Third, *moral wrong* implicates multiple LGBTQ+ community segments. Lesbian, gay, bisexual, and transgender people may all partake in “homosexual” behavior and relationships. Therefore, our outcome measures attitudes toward large segments of the LGBTQ+ umbrella. Given the outcome characterizes a negative attitude toward LGBTQ+ community segments, if we uncover support for **H1**, the *post-Shepard* coefficient would be *negative*.

Our approach has shortcomings we attempt to assuage. First, given the absence of auxiliary data on attention to the murder, we cannot be certain respondents “received the treatment.” Therefore, we interpret *post-Shepard* as an ITT effect. However, Figure 6 suggests the murder received significant media attention such that it might shift the mass public’s attitudes.

Second, given possible differences in sampling between the two surveys, our statistical conclusions may be a function of sample composition. Balance tests on baseline covariates between the two surveys for each outcome demonstrate limited covariate imbalance (Figure 7, Panel A), suggesting sample composition may not drive our results.

Third, unlike Studies 1 and 2, we cannot assess an immediate effect of anti-gay violence exposure even though the surveys we use were fielded near Shepard’s murder. There are 4 (Jun.-Oct. 1998) months in between the surveys with the *moral wrong* outcome. Therefore, our *post-Shepard* estimates may be due to intervening factors or secular progressive time trends. However, there are no other instances of anti-gay violence in this time period with

the level of media coverage Shepard's murder garnered in between the field periods (Figure 6). Crowdsourced evidence suggests the last prominent instance of anti-LGBTQ+ violence prior to Shepard's murder was not between June-October of 1998, but on February 1997 (i.e. the Otherside Lounge Bombing).²⁸ Indeed, a more precise assessment of whether there was coverage of anti-gay hate crimes in the New York Times between June and October 1998 shows that there were *zero* articles related to anti-gay hate crimes in June-September 1998. Conversely, on the month of Shepard's murder (October 1998), there were 17 NYT articles related to anti-gay hate crimes, suggesting limited intervening events explaining our *post-Shepard* coefficient estimates (Figure D36).

Moreover, we rule out if our results are due to secular outcome time trends by conducting a temporal placebo test and demonstrating *moral wrong* levels do not change between Apr. 1997-Jun. 1998 (Figure 7, Panel B).²⁹ These results are important since they suggest prominent pre-study events, such as Ellen DeGeneres' televised coming out in April 1997, are not driving our results. In summary, despite Study 3's shortcomings, we believe the design provides sufficient complementary evidence to Studies 1–2 along with suggestive evidence our theory is generalizable beyond Pulse.

5.1.2 Results

Consistent with **H1**, Figure 7, Panel B shows respondents interviewed *post-Shepard* were 10 percentage points less likely to report homosexuality is morally wrong with or without covariate adjustment, 20% of the outcome standard deviation ($p < 0.001$).

We conduct several falsification tests on outcomes unrelated to gay people or rights but related to other marginalized groups to rule out secular supportive trends toward marginalized groups that may drive our results (Figure 7, Panel C).³⁰ Only 4/18 outcomes are statistically significant and the *post-Pulse* coefficient is not consistently in support of non-LGBTQ+

²⁸https://en.wikipedia.org/wiki/History_of_violence_against_LGBT_people_in_the_United_States

²⁹See Section D.2 for more details on the temporal placebo test.

³⁰See Appendix D.6 for more details on the falsification test outcomes.

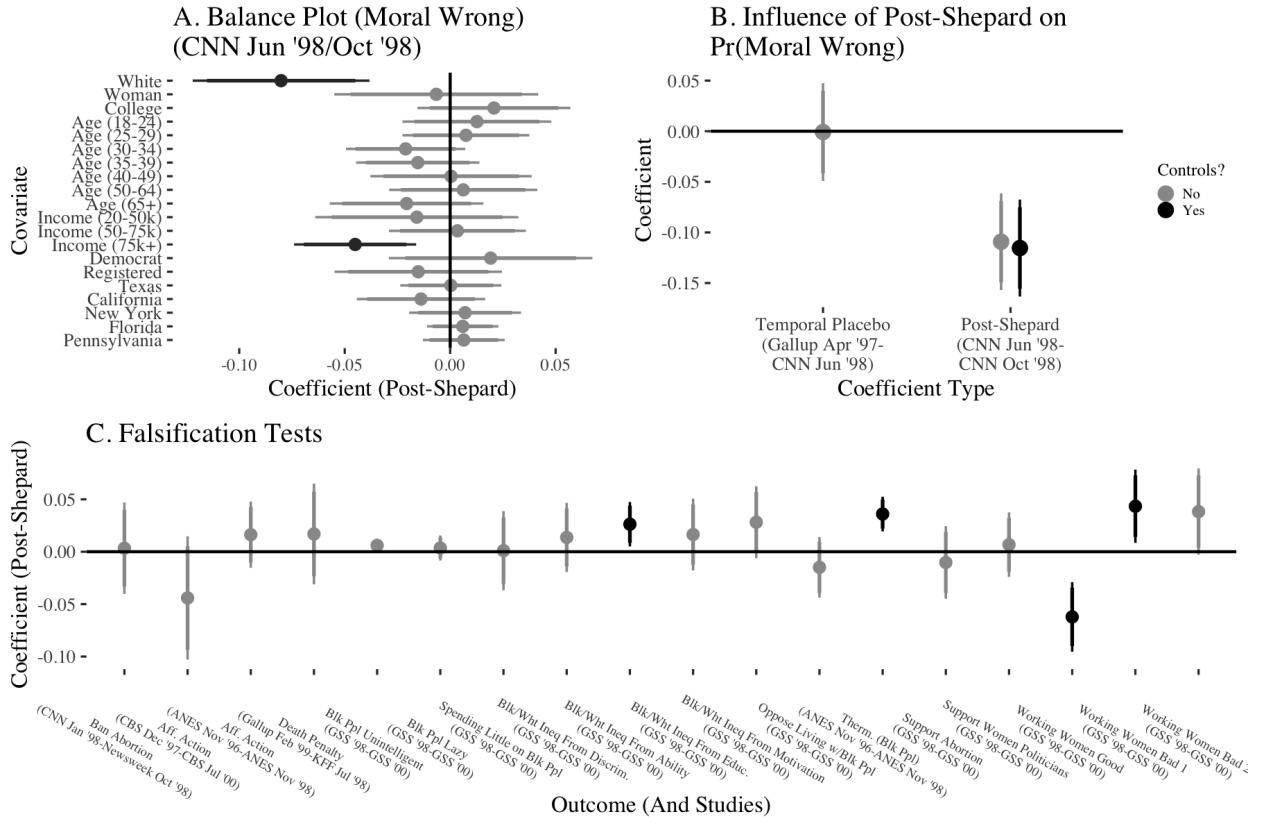

Figure 7: Respondents Interviewed *Post-Shepard* Were Less Likely To Believe Homosexuality is Morally Wrong. Panel A characterizes covariate balance between respondents interviewed before and after Shepard's murder. Black coefficients are statistically significant, grey otherwise. Panel B characterizes a) the influence of being interviewed on June 1998 relative to April 1997 on the belief homosexuality is morally wrong (temporal placebo) and b) the influence of being interviewed *post-Shepard* on *moral wrong*. Panel C characterizes falsification tests assessing the influence of *post-Shepard* non-LGBTQ+ group attitudes. 95% CIs displayed derived from robust SEs. See Tables D55, D56, D57, and D58 for regression tables on balance tests, the temporal placebo, the *post-Shepard* coefficient estimates, and falsification tests.

marginalized groups, suggesting no systematic secular trend favoring marginalized groups. The Black feeling thermometer shifts in a favorable direction for Black people *post-Shepard*. However, the mass public increasingly attributes Black-White inequality to in-born ability *post-Shepard*, not discrimination, an unfavorable position toward Black people. The mass public is also less likely to believe women can establish a warm relationship with their children and more likely to believe their children will suffer if they work (“working women good”, “working women bad 1”) *post-Shepard*, both unfavorable attitudinal shifts toward women.

Event Study (Moral Wrong)

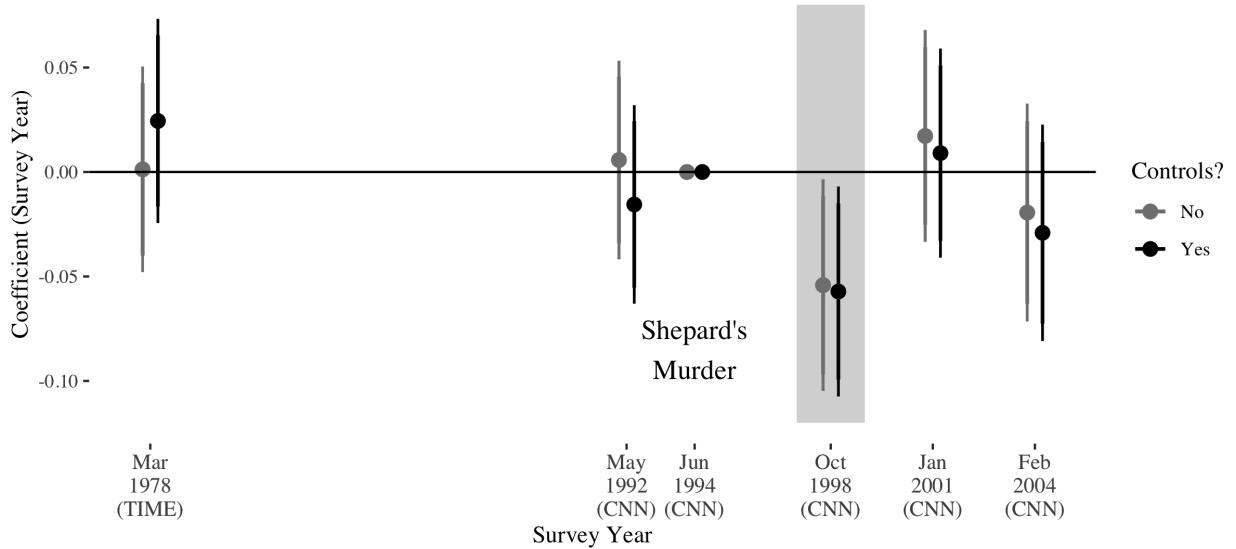

Figure 8: Belief in *Moral Wrong* is Stable Between 1978-2004 With the Exception of the Moment Shepard Was Murdered. Reference study is the 1994 CNN poll. Color denotes the inclusion/exclusion of controls adjusting for age, education, gender, partisanship, and race. Shaded estimate denotes moment of Shepard's murder (Oct. 1998). All estimates use survey weights. All covariates scaled between 0-1. See Table D59 for a regression table characterizing this figure. 95% CIs displayed derived from robust SEs.

5.1.3 Temporal Persistence

To assess the temporal persistence of attitudinal shifts toward gay people *post-Shepard*, we identify 6 surveys between 1978-2004 where the *moral wrong* item was asked,³¹ allowing us to evaluate temporal trends in the mass public's belief that homosexuality was morally wrong pre- and *post-Shepard*. We do not use the CNN June 1998 poll on Figure 8. This is because the *moral wrong* item in the CNN June 1998 poll references “homosexual behavior” as opposed to “homosexual relationships between consenting adults.” Therefore, we focus on surveys with *moral wrong* outcome items using the “consenting adults” wording for the event study. However, two concerns may arise. First, one may be concerned using the “consenting adults” item in our main analysis on Figure 7 may inflate the *post-Shepard* coefficient since it may make respondents more comfortable with “homosexual relationships.”

³¹See Section D.5 for details on the 6 surveys used for the temporal persistence analysis.

Yet, we still observe a negative, significant, *post-Shepard* coefficient (-0.06) from the event study comparing a CNN 1994 poll to the CNN October 1998 poll. Second, one may be concerned the alternative analysis comparing polls between 1994-1998 may be biased by secular attitudinal time trends in support of gay people. But the absence of temporal trends in the “homosexual behavior” items (Figure 7, Panel B) between 1997-1998 suggests this is unlikely. In addition, the stability of the “consenting adults” version of the *moral wrong* outcome from 1978-1994 suggests secular attitudinal time trends are not influencing the *post-Shepard* coefficient. However, we caveat our findings by noting the distinct possibility there is an unobserved trend that exists only for the “homosexual behavior” outcome that does not exist for the “consenting adults” outcome. But this may be unlikely because we may expect prosocial secular trends toward people engaged in “homosexual relationships between consenting adults” than toward people engaged in “homosexual behavior” because of the clarity related to “consent.”

Figure 8 displays event study estimates comparing *moral wrong* levels in 5 surveys between 1978-2004 to a survey fielded prior to Shepard’s murder in 1994. From 1978-1994, belief in the notion homosexuality is morally wrong is remarkably stable. Respondents surveyed in 1994 are not statistically distinct from respondents surveyed in 1992 or 1978. Consistent with our initial temporal placebo test, these findings suggest an absence of progressive attitudinal trends toward gay people prior to Shepard’s murder. However, in October 1998, immediately after Shepard’s murder, there is a statistically distinguishable decrease in the belief homosexuality is morally wrong. But, the mass public’s beliefs in *moral wrong* reverses back to levels prior to Shepard’s murder by 2001 and 2004. Consistent with **H2** and Studies 1-2, our results suggest Shepard’s murder motivated a decrease in negative beliefs concerning “homosexuals,” but this decrease was not temporally sustainable.

6 Limitations and Additional Robustness Checks

Our analyses pose limitations future research should resolve. First, although we provide supplemental media data, manipulation checks, and falsification tests on “treatment”-irrelevant outcomes to demonstrate respondents likely perceived and responded to violence against LGBTQ+ people in a theoretically consistent manner, we cannot be certain survey respondents “received the treatment.” Future research should use designs encouraging stronger treatment reception (e.g. survey experiments) to assess if our findings replicate or are an underestimate of the effect and/or temporal persistence of violence exposure. However, unlike designs offering stronger treatment reception, an advantage of our design(s) is that they derive effects based on “real-world” and externally valid instances of violence against LGBTQ+ group members.

Second, we only evaluate the attitudinal consequences of civilian-perpetrated violence against LGBTQ+ group members, not other marginalized groups. We have done our due diligence to replicate our findings across two prominent instances of violence against LGBTQ+ group members, but future work should assess if salient civilian violence against other groups (i.e. immigrants, Black people, Asians, Latinxs, women) differentially motivates prosocial responses.

Third, our evidence is light on mechanisms. Our design is advantageous in that we can assess the effects of violence on prosocial attitudes in an uncontrolled environment with plausible identification assumptions, undercutting demand effects or external invalidity. But, our data were not directly collected to test our hypotheses, making mechanism tests difficult.

Nevertheless, honing in on TAPS,³² we evaluate several mechanisms. Prior research suggests shared marginalization experiences may encourage empathetic responses to group-targeted violence (i.e. being a woman, Latino, or Black, see Sirin et al. (2021)). Prior research also suggests social contact with LGBTQ+ group members may prime individuals to adopt

³²We focus on TAPS due to the wide array of covariates collected we can use to assess mechanisms (e.g. zipcode indicators).

pro-LGBTQ+ attitudes in response to violence against LGBTQ+ people (Tadlock et al., 2017). Moreover, liberals may be more inclined to support LGBTQ+ in the aftermath of violence against LGBTQ+ people (Flores, 2014). However, we do not find respondents who are marginalized group members (Table B15, Models 1-3), live in areas with more LGBTQ+ (and ostensibly have more contact with LGBTQ+, Models 4-5), or liberal are more inclined to support SSM *post-Pulse* (Model 8).³³ Additionally, we assess if the *post-Pulse* coefficient is heterogeneous by imputed baseline attitudes for Studies 1-2 to assess if the influence of violence is stronger among already prosocial individuals or individuals with attitudes that have space to travel.³⁴ We do not find *post-Pulse* coefficients are heterogeneous by baseline imputed attitudes. These tests of potential mechanisms and sources of heterogeneity suggest the mass public largely responded in a *homogeneous* manner to the Pulse massacre. Given the Pulse massacre's salience, homogeneous effects may be a function of common information exposure (Page and Shapiro, 2010).

Future research should test other mechanisms and sources of heterogeneity. Social psychological insights are promising. Violence exposure's influence on prosocial beliefs and their temporal sustainability may be mediated through positive emotional responses toward marginalized groups (e.g. empathy, sympathy, anger, and guilt) (Branscombe and Miron, 2004; Iyer et al., 2007; Harth et al., 2008). Additionally, future research should assess how media frames condition the mass public's attitudinal responses. In the cases of Shepard's murder and Pulse, the media and political elites framed the victims sympathetically (instead of unsympathetically). At the same time, prior research suggests the media used episodic frames focusing on perpetrator motivations instead of thematic frames emphasizing societal queerphobia as a root cause of violence against LGBTQ+ people (Ott and Aoki, 2002; Zahzah, 2019). It may be prudent to evaluate if framing differences condition prosocial responses and their temporal durability.

³³We also use the PI S-IAT data to demonstrate being a marginalized group member or liberal does not moderate the influence of *post-Pulse* on the *D-Score* or *heterocentrism* (Table C49).

³⁴Imputed baseline attitudes are predicted outcome attitudes in the absence of the Pulse massacre conditional on the control covariates used in Studies 1-2.

Third, although our outcomes implicate several LGBTQ+ community segments, they do not explicitly reference broader segments (e.g. transgender, non-binary, asexual, pansexual, intersex, or two-spirit people).³⁵ Future research should assess if violence against some or multiple LGBTQ+ community segments generates prosociality, even if temporally fickle, on attitudinal dimensions explicitly referencing broader LGBTQ+ segments, who often face further societal derogation (Norton and Herek, 2013).

To this end, we conduct an additional study leveraging both the 2022 Project Implicit Sexuality and *Transgender* IAT surveys.³⁶ We use these data in addition to another unexpected-event-during-survey-design to assess the influence of the November 19, 2022 Club Q shooting, a civilian-perpetrated mass shooting against LGBTQ+ people at a Colorado Springs, CO LGBTQ+ nightclub where 5 people were killed, on attitudes toward gay, lesbian, and bisexual people (i.e. sexuality *D-score*, *heterocentrism*, and *straight bias*) in addition to transgender people explicitly (i.e. transgender *D-score*, *ciscentrism*, and *cis bias*). We find no evidence the shooting motivated prosocial attitudes in the short-term toward these groups (Figure F45). We do not interpret these null results as inconsistent with the spirit of Studies 1-3, which ultimately show the adoption of prosocial attitudes toward LGBTQ+ group members is temporally fickle. However, we want to highlight two potential reasons the Club Q shooting did not motivate short-term prosocial attitudes unlike the Pulse massacre and Shepard's murder. First, salience. Media coverage of Club Q is lower than the Pulse massacre and Shepard's murder in the two months after the shooting, so the mass public may have not received the treatment as strongly (Figure F47).³⁷ Moreover, Google Trends data suggests the mass public paid less attention to the Club Q shooting relative to the Pulse massacre (Figure F46). Second, elite-level political polarization over LGBTQ+ issues. For example, in the past few years, Republican-controlled state governments have increasingly

³⁵Arguably, our outcomes implicate most LGBTQ+ members. Of LGBT, 91% are gay, lesbian, or bisexual. The other 9% are transgender. See: <https://williamsinstitute.law.ucla.edu/publications/how-many-people-lgbt/>

³⁶Project Implicit started collecting transgender attitude data in 2020.

³⁷Media coverage is measured by the number of New York Times articles related to each event after two months post-event.

introduced anti-LGBTQ+ legislation relative to Democratic-controlled state governments (Figure F49). Anecdotal evidence suggests the Republican party's rhetoric on LGBTQ+ people, and especially transgender people, has become increasingly vitriolic in the last few years (e.g. characterizing LGBTQ+ people as “groomers”).³⁸ Prior research demonstrates mass attitudes are stable in politically polarized contexts, where elite-level messaging may supersede the prospect for attitudinal shifts in response to violence against LGBTQ+ people (Lewis et al., 2022). Future research should continue to assess the attitudinal consequences of high-profile violence against the LGBTQ+ community on attitudes toward community segments that are not just gay, lesbian or bisexual.

Fourth, another limitation is that we only focus on civilian violence that is *high-profile* and *salient*. This could be an advantage since the Pulse massacre and Shepard's murder are ostensibly “most likely” cases which received a high degree of media attention (facilitating treatment reception) and were unexpected events (facilitating causal identification). Indeed, using crowdsourced data recording violent incidents against LGBTQ+ people between 2000-2016,³⁹ the Pulse massacre and Shepard's murder are significantly more salient than other incidents (Section E). For example, there are 1130 and 1720 New York Times hits related to Shepard's murder and the Pulse massacre, but only 25 hits for the next most salient instance of violence against LGBTQ+ between 2000-2016 (i.e. Mark Carson's murder on May 2013, see Figure E40). Moreover, consistent with the notion lower salience reduces treatment reception, these other violent events have largely null effects on mass attitudes toward gay, lesbian, and bisexual people (Figure E42). On the other hand, *direct observation* of smaller-scale quotidian violence against LGBTQ+ group members (e.g. observing hate crimes, assault, verbal abuse, micro-aggressions) may have a stronger and more temporally durable impact on prosocial beliefs. Future research should explore how different types of violence exposure motivates prosocial beliefs.

³⁹https://en.wikipedia.org/wiki/History_of_violence_against_LGBT_people_in_the_United_States

Fifth, our study only explores attitudinal shifts, not behavior. Behavioral shifts may not be commensurate with attitudinal changes. However, we do not believe our lack of emphasis on behavior is a shortcoming. The fickle attitudinal shifts we identify suggest the mass public may have engaged in short-term impression management until perceptibly anti-LGBTQ+ violence was no longer salient, making them more comfortable to express their original beliefs, and implying that behavioral shifts are unlikely. Nevertheless, we explore if the Pulse massacre motivated different pro/anti-LGBTQ+ behaviors and find mixed evidence on whether the massacre motivated pro/anti-LGBTQ+ behaviors (see Section A.11 for details).

7 Discussion and Conclusion

Across three studies and two contexts, we provide evidence that exposure to salient and indirect civilian violence toward LGBTQ+ group members increases prosocial attitudes toward LGBTQ+ community segments. However, consistent with *issue-attention cycle* and *focusing event* theory, along with insights on the stability of group-oriented attitudes, these prosocial responses are not temporally sustainable.

Our study teaches us how the mass public might respond to prominent instances of civilian-perpetrated violence against marginalized groups. In the U.S., these events are common, including, but not limited to, the 1963 Birmingham bombing, 1996 James Byrd murder, 2015 Charleston Church shooting, 2015 Stanford sexual assault case, 2019 El Paso shooting, 2021 Atlanta spa shooting, and the 2022 Buffalo shooting. Our evidence provides a nuanced understanding of attitudinal reactions to these violent incidents. Consistent with work on anti-Black state violence (Reny and Newman, 2021; Sigelman et al., 1997), the mass public and dominant group members may express positive attitudes toward marginalized groups in the immediate aftermath of their subjection to civilian violence. However, consistent with prior evidence demonstrating fickle attitudinal shifts after unexpected violent events (Tuch and Weitzer, 1997; Birkland and Lawrence, 2009; Chudy and Jefferson, 2021; Nguyen

et al., 2021), a key contribution inherent to this study is that we repeatedly demonstrate indirect exposure to salient civilian violence against marginalized groups may not serve as a sustainable moment of introspection undercutting negative attitudes toward these groups.

What would generate temporally sustainable effects? Birkland and Lawrence (2009) suggest sustained media attention over long time periods may motivate sustained mass attitudinal shifts. Disturbingly, recurrence of salient violent events may be a key condition for temporally sustainable prosocial shifts. Additionally, implicit in our theory is that political elites may play a role in making violent incidents salient. Therefore, elites who continue to strategically amplify issues related to a specific event after an event loses salience may help to facilitate sustained attitudinal shifts (Ciuk and Yost, 2016). Moreover, perhaps direct or proximal (e.g. friends, family), as opposed to indirect (e.g. via media), exposure to violence is necessary to durably shift mass attitudes. Prior work shows direct violence exposure may produce temporally sustainable consequences on mass attitudes and behavior (Lupu and Peisakhin, 2017; Mironova and Whitt, 2018; Hadzic et al., 2020). Prosocial consequences may also be temporally durable conditional on victim or perpetrator characteristics, and the scale of violence. We leave it up to future research to continue to assess the possibility for temporally durable effects.

A Pulse Context

A.1 Demonstrating Pulse Was Salient

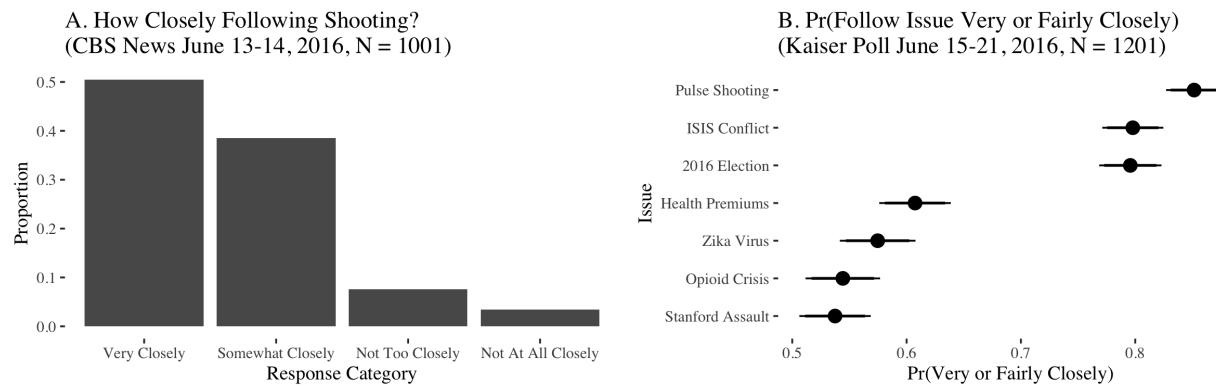

Figure A1: Survey Data Demonstrate the Pulse Massacre Was Salient. Panels A and B display how closely respondents were following the Pulse shooting in a June 2016 CBS and Kaiser poll respectively. Panel B compares attention to Pulse (x-axis) relative to other issues (y-axis). All estimates are population weighted. 95% CIs displayed from 1000 bootstrap simulations. See Section A.6 for more details on Figure A1 polls.

A.2 Media Coverage Over Time

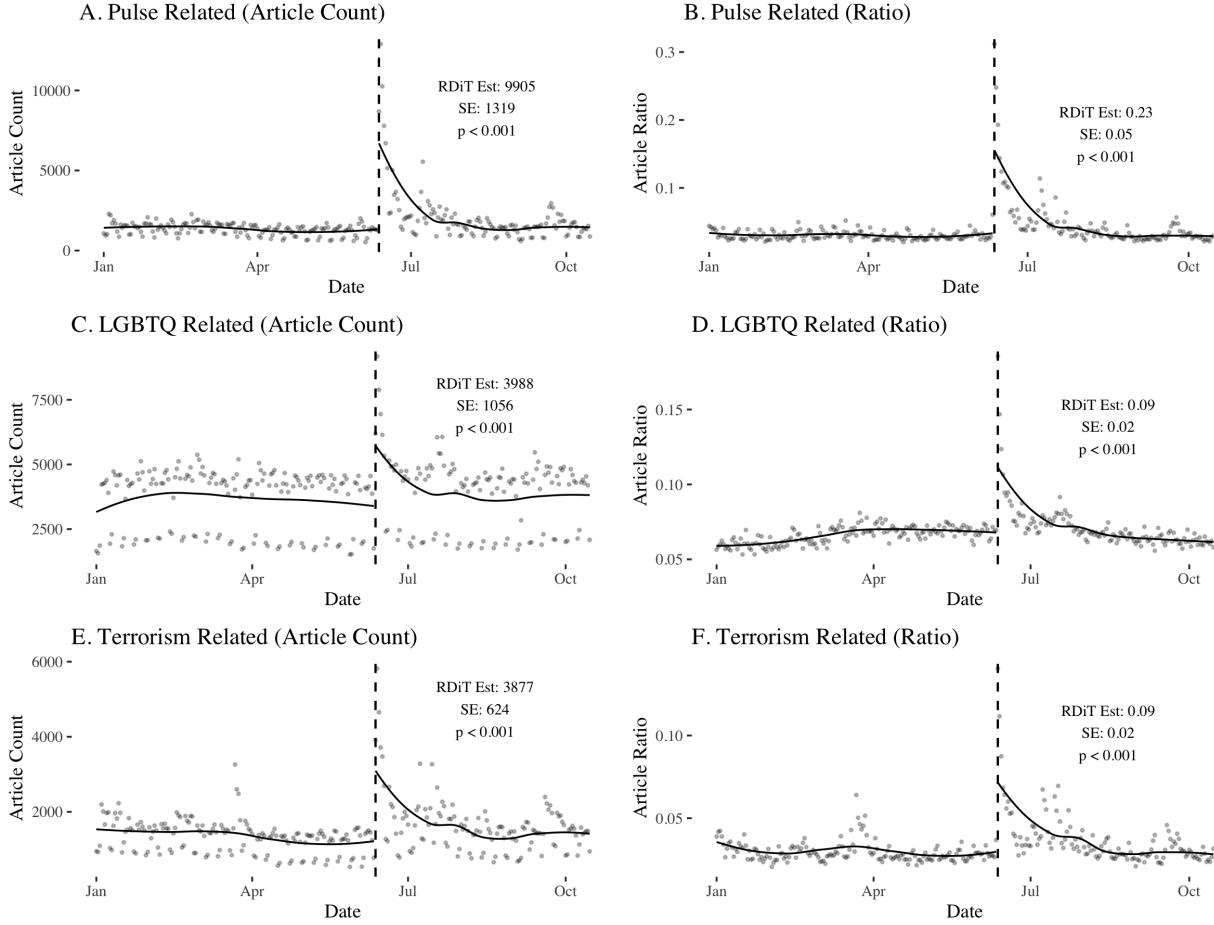

Figure A2: Media Coverage of Topics Related to the Pulse Massacre Over Time. Panels A, C, and E display the count of Pulse-, LGBTQ-, and terrorism-related stories between January–October 2016. Panels B, D, and F display the ratio of Pulse-, LGBTQ-, and terrorism-related stories relative to the total number of stories in digital news. Loess models fit on each side of the moment the massacre occurs. Annotations denote RDiT estimates for the effect of Pulse on the article count and ratio using MSE optimal bandwidth selection (Calonico et al., 2015) (running variable degree = 1). See Appendix A.7 for more details on Figure A2 data.

A.3 Search Behavior Over Time

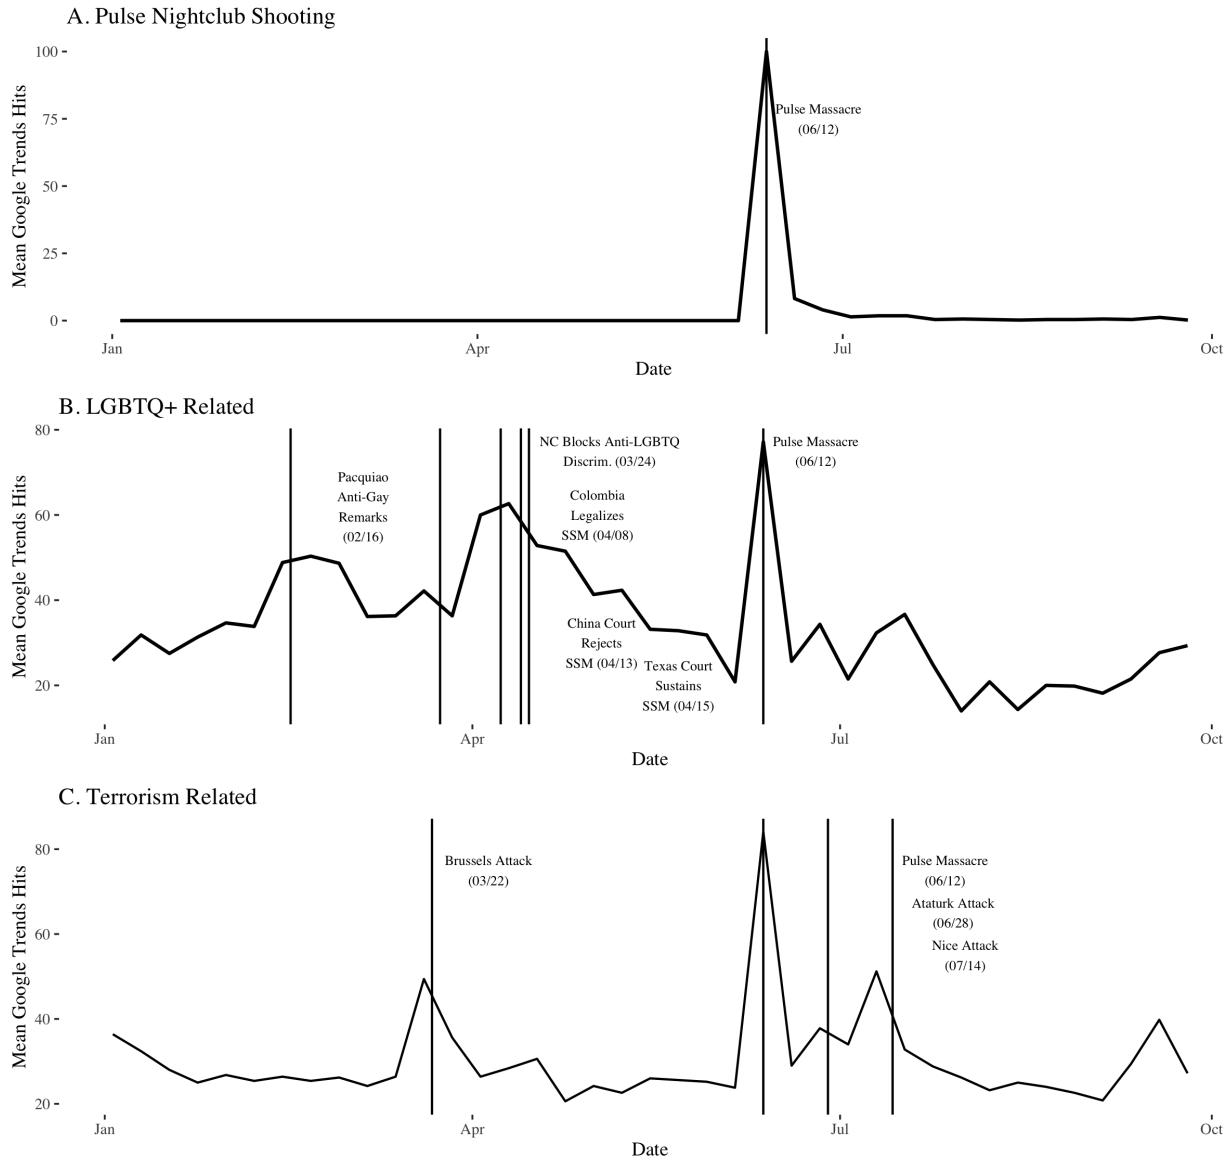

Figure A3: Search Behavior From Google Trends Demonstrates the Pulse Massacre Was Salient and Unexpected. Panels A, B, and C display the average search intensity for Pulse massacre-, LGBTQ-, and terrorism-related terms between January–October 2016. Vertical lines and annotations denote key events related to respective topics. See Appendix A.9 for more details on Figure A3 data.

A.4 Demonstrating Public Perceived Pulse

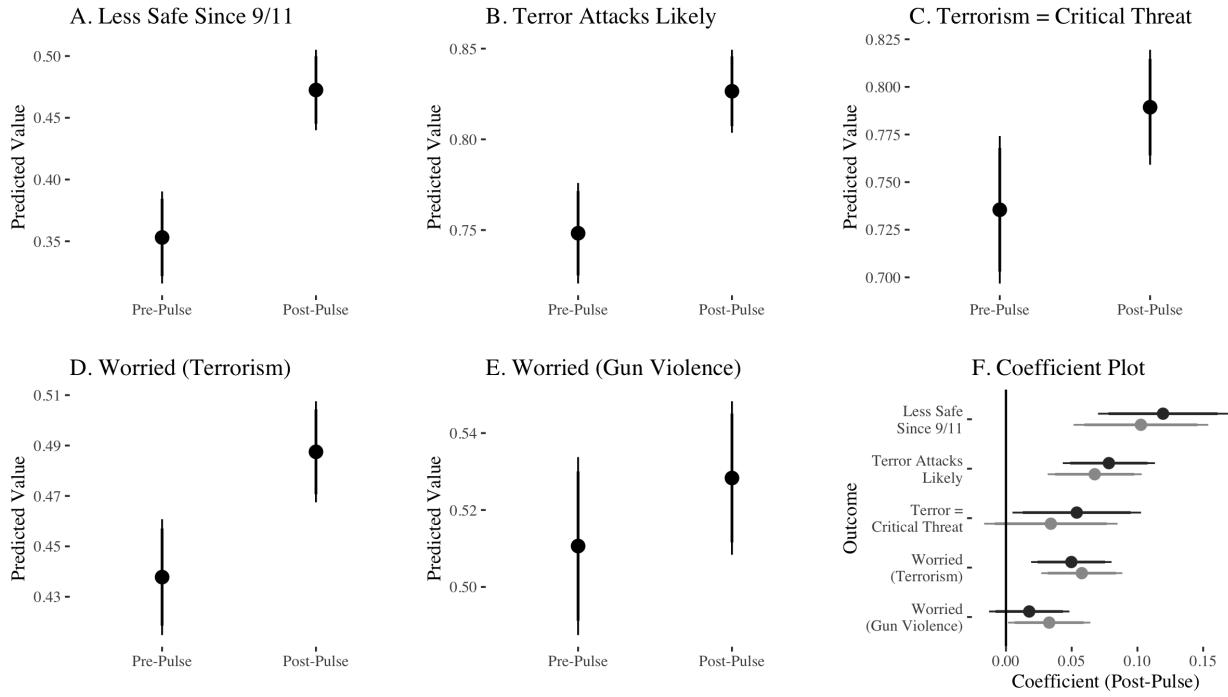

Figure A4: The Pulse Massacre Was Perceived by the Mass Public. Panels A-E characterize predicted values of belief country is less safe since 9/11, terror attacks are likely in the future, international terrorism is a critical threat, worry about terrorism, and worry about gun violence respectively. Panel F characterizes the the influence of Pulse (x-axis) on the aforementioned outcomes (y-axis) adjusting and not for imbalanced covariates (black = with controls, grey otherwise, see Figure A6 for balance plot). All covariates rescaled between 0-1. 95% CIs displayed derived from HC2 robust standard errors. See Section A.8 for more details on Chicago Council data. See also Table A1.

A.5 Demonstrating Public Perceived Massacre as Hate Crime

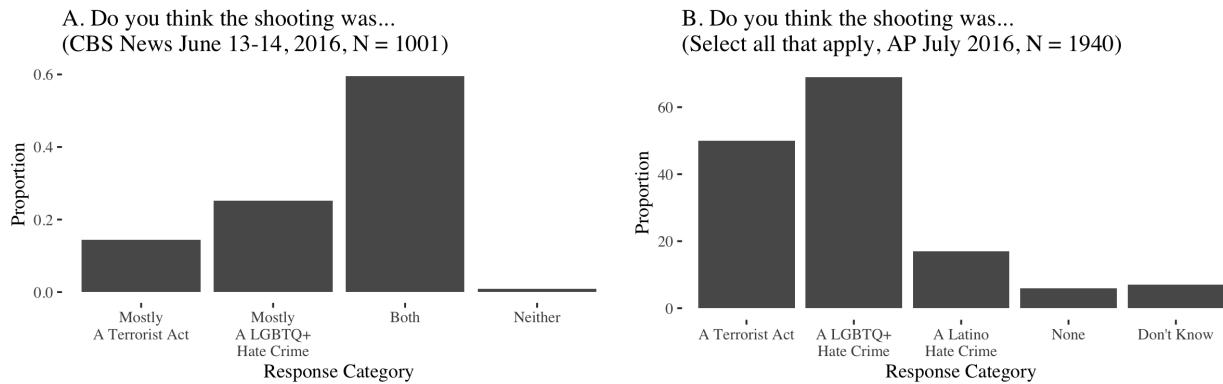

Figure A5: The Pulse Massacre Was Perceived as Targeted Anti-LGBTQ+ Violence. Panels A and B display beliefs the public felt the shooting was an anti-LGBTQ+ hate crime in a June 2016 CBS poll (Panel A) and July 2016 AP poll (Panel B). All estimates are population weighted.

A.6 Salience Data Details

CBS News June 13-14 Poll is a nationally representative adult survey ($N = 1001$). The poll used a random digit dial methodology. Interviews were conducted in English and Spanish using live interviewers. The data are weighted to reflect U.S. census figures on demographic variables. The margin of error for the weighted data is ± 4 percentage points. The item of interest on Figure A1, Panel A is: “How closely have you been following news about the recent shooting at a nightclub frequented by gays and lesbians in Orlando, Florida where at least 49 people were killed – very closely, somewhat closely, not too closely, or not at all closely?” The item of interest on Figure A5, Panel A is “Do you think the shooting at the nightclub in Orlando, Florida was (mostly a terrorist act), (mostly a hate crime against people who are gay and lesbian), or both?”

Kaiser Family Foundation June 15-21 Poll is a nationally representative adult survey ($N = 1201$). The poll used a random digit dial methodology. The item of interest on Figure A1, Panel A is: “How closely have you been following news about the recent shooting at a nightclub frequented by gays and lesbians in Orlando, Florida where at least 49 people were killed – very closely, somewhat closely, not too closely, or not at all closely?”

A.7 Media Attention Data Details

We acquired media data on the daily number of web articles related to the topics of interest from Mediacloud’s Explorer Search Tool (<https://explorer.mediacloud.org/>) from January 1, 2016 to October 15, 2016 to generate Figure A2. The reason we do not include data after October 15, 2016 in our analyses is because we do not want our analyses to be perturbed by the 2016 election, which increased attention to LGBTQ-related topics due to Trump’s anti-LGBTQ positions. The two measures of media attention we evaluate are the *article count* and *article ratio*. The article count is the raw number of web articles including a specific search term(s). The article ratio is the number of web articles including a specific search term(s) normalized over the total number of web articles.

We acquire article count and ratio data on three topics.

1. Pulse-related topics
2. LGBTQ-related topics
3. Terrorism-related topics.

Pulse-related topics are the article count sum and article ratio mean for queries on the terms “orlando massacre,” “orlando shooting,” “pulse nightclub,” “pulse shooting.” LGBTQ-related topics are the article count sum and article ratio mean for queries on the terms “anti-gay,” “anti-lgbt,” “gay marriage,” “gay rights,” “hate crime,” and “same sex marriage.” Terrorism-related topics are the article count sum and ratio mean for queries on the terms “isis,” “lone wolf,” “mass shooting,” “terror attack,” and “terrorism.”

A.8 Chicago Council Study

A.8.1 Data Details

The Chicago Council on Global Affairs Poll is a nationally representative adult survey fielded between June 10-26, 2016 ($N = 2061$). The survey was conducted by GfK Knowledge Networks. The margin of sampling error for the weighted data is ± 2.4 percentage points. The data are subsetted to respondents who took between 10-60 minutes to complete the roughly 120 item survey ($N = 1704$).

A.8.2 Outcome Items

“Less Safe Since 9/11” Do you think that, as a country, we are more safe, about as safe, or less safe than we were before the terrorist attacks of September 11th, 2001? 1) More safe, 2) About as safe 3) Less safe. Measured binary = 1 if respondent indicates “less safe.”

“Terror Attacks Likely” How likely is it that occasional acts of terrorism in the U.S. will be part of life in the future? 1) Very likely, 2) Somewhat likely, 3) Not very likely, 4) Not at all likely. Re-scaled from 0-1 with 1 = very likely.

“Terrorism = Critical Threat” Below is a list of possible threats to the vital interest of the United States in the next 10 years. For each one, please select whether you see this as a critical threat, an important but not critical threat, or not an important threat at all: International terrorism. 1) Critical threat, 2) Important but not critical threat, 3) Not an important threat. Measured binary = 1 if respondent indicates “critical threat.”

“Worried (Terrorism)” Are you very worried, somewhat worried, not very worried or not worried at all that: You or someone you know will be the target of a terrorist attack. 1) Very worried, 2) Somewhat worried, 3) Not very worried, 4) Not at all worried. Re-scaled from 0-1 with 1 = very worried.

“Worried (Gun Violence)” Are you very worried, somewhat worried, not very worried or not worried at all that: You or someone you know will be the target of gun violence. 1) Very worried, 2) Somewhat worried, 3) Not very worried, 4) Not at all worried. Re-scaled from 0-1 with 1 = very worried.

A.8.3 Balance Plot

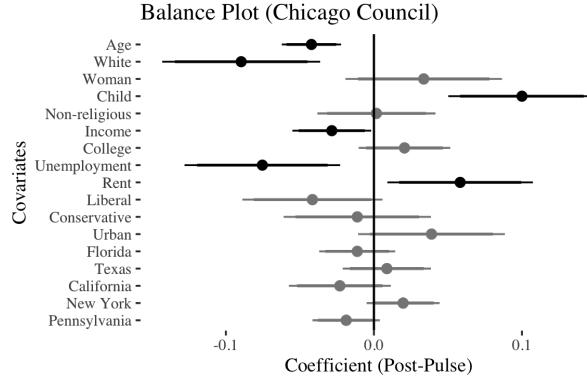

Figure A6: Covariate Balance for Survey Respondent Characteristics Before and After the Pulse Massacre in the Chicago Council on Global Affairs Survey (June 2016). Black coefficients are statistically significant, grey otherwise. All estimates use post-stratification survey weights to ensure representativeness. All covariates scaled between 0-1. 95% CIs displayed derived from HC2 robust standard errors.

A.8.4 Regression Table

Table A1: The Pulse Massacre Was Perceived by the Mass Public

	Less Safe (1)	Safe (2)	Terror (3)	Likely (4)	Terror (5)	Threat (6)	Worry (7)	(Terror) (8)	Worry (9)	(Gun Violence) (10)

A.9 Google Trends Data Details

We acquired Google Trends search data at the weekly level from the `gtrendsR` R package. We generate three different search intensity measures capturing interest in the Pulse nightclub shooting, LGBTQ-related issues, and terrorism-related issues. The Pulse-related issue measure is the average of the Google Trends search intensity measures for separate queries on the “pulse nightclub,” “pulse shooting,” “orlando massacre,” and “orlando shooting.” The LGBTQ-related issue measure is the average of the Google Trends search intensity measures for separate queries on “gay rights,” “gay marriage,” “same-sex marriage,” “hate crime,” “anti-gay,” and “anti-lgbt.” The terrorism-related issue measure is the average of the Google Trends search intensity measures for separate queries on “terrorism,” “terror attack,” “lone wolf,” “ISIS,” and “mass shooting.”

The search intensity measure is the number of total searches divided by the total searches of the geography (United States) and time range (January 1, 2016-October 1, 2016) it represents to compare relative popularity. The numbers are scaled on a range of 0-100 based on a topic’s proportion to all searches on all topics. For more information see <https://support.google.com/trends/answer/4365533?hl=en>

A.10 Hate Crime Perceptions Data Details

The AP/Black Youth Project July Poll is a nationally representative adult survey ($N = 1940$) fielded between July 9, 2016 and July 12, 2016. The data are weighted to reflect U.S. census figures on demographic variables. The margin of error for the weighted data is ± 4 percentage points. The item of interest on Figure A5, Panel B is: “You may recall that last month (June 2016), 49 people were shot and killed (and 53 people were injured) by 29-year-old Omar Mateen at Pulse nightclub in Orlando, Florida. From what you remember, do you think the shooting at the nightclub in Orlando, Florida was a terrorist act, a hate crime against people who are gay, lesbian, bisexual, and transgender, a hate crime against Latinos/Hispanics, or none of the above? Please select all that apply.”

A.11 Behavioral Shifts Post-Pulse

We assess if the Pulse massacre motivated three different pro/anti-LGBTQ+ behaviors: anti-LGBTQ+ hate crimes, donations to Florida-based pro-LGBTQ+ organizations, and blood donations. We find the massacre motivated an increase in anti-LGBTQ+ hate crimes, consistent with prior research suggesting violence has a contagious effect (Section A.11.1) (Towers et al., 2015); no increase in monetary donations to Orlando LGBTQ+-serving organizations (Section A.11.7); and an increase in blood donations for victims (Section A.11.8). These findings suggest the massacre motivated both pro- and anti-social *behavior*, but given we use aggregate data, we cannot determine if this is due to behavioral *changes* or *priming* of those who are predisposed to either be anti-social or pro-social toward LGBTQ+ people. Future research should continue to explore the behavioral consequences of exposure to salient civilian violence against marginalized groups in addition to attitudinal consequences.

A.11.1 Anti-LGBTQ+ Hate Crimes: Details

We evaluate if the Pulse massacre motivated anti-LGBTQ+ hate crimes, consistent with prior research suggesting mass violence may have a contagion or “copy-cat” effect (Towers et al., 2015). To assess trends in hate crimes, we use data from the FBI Uniform Crime Report on hate crimes across the United States at the daily level between January 1, 2016, and December 31, 2016. Importantly, because the Pulse massacre was understood as a terrorist attack not necessarily motivated by anti-LGBTQ+ bias, it was not classified as a hate crime, even though it was perceived by the mass public as an anti-LGBTQ+ hate crime (Figure A5). Therefore, our analyses assessing the effect of the Pulse massacre on hate crimes is not driven by the massacre itself.

Figure A7 displays anti-LGBTQ+ (Panel A), anti-Black (Panel B), anti-Jewish (Panel C), and anti-Latino (Panel D) hate crimes during 2016 at the daily-level over time. The descriptive statistics suggest anti-LGBTQ+ hate crimes increased for a brief period after the Pulse massacre, but not anti-Black, anti-Jewish, and anti-Latino hate crimes.

Regression discontinuity-in-time estimates using the Calonico et al. (2015) optimal bandwidth selection approach corroborates the descriptive statistics (Figure A8). Immediately after Pulse, there’s an increase in roughly 2 daily anti-LGBTQ+ hate crimes. However, there is 0 increase in the number of daily anti-Black, anti-Jewish, or anti-Latino hate crimes. These findings are robust to a variety of kernel and polynomial specifications for the running variable (days to Pulse).

The regression discontinuity estimates characterizing are robust. They hold using a variety of bandwidths from 10-100 days (Figure A9), and many of the coefficients are larger than at least 90% of the effects from pre-treatment placebo discontinuities (Figure A10). These effects are also not driven by Pride month, since they do not manifest in years prior to Pulse (2010-2015) or years after Pulse (2017-2019) (Figure A11).

A.11.2 Anti-LGBTQ+ Hate Crimes: Descriptive Statistics

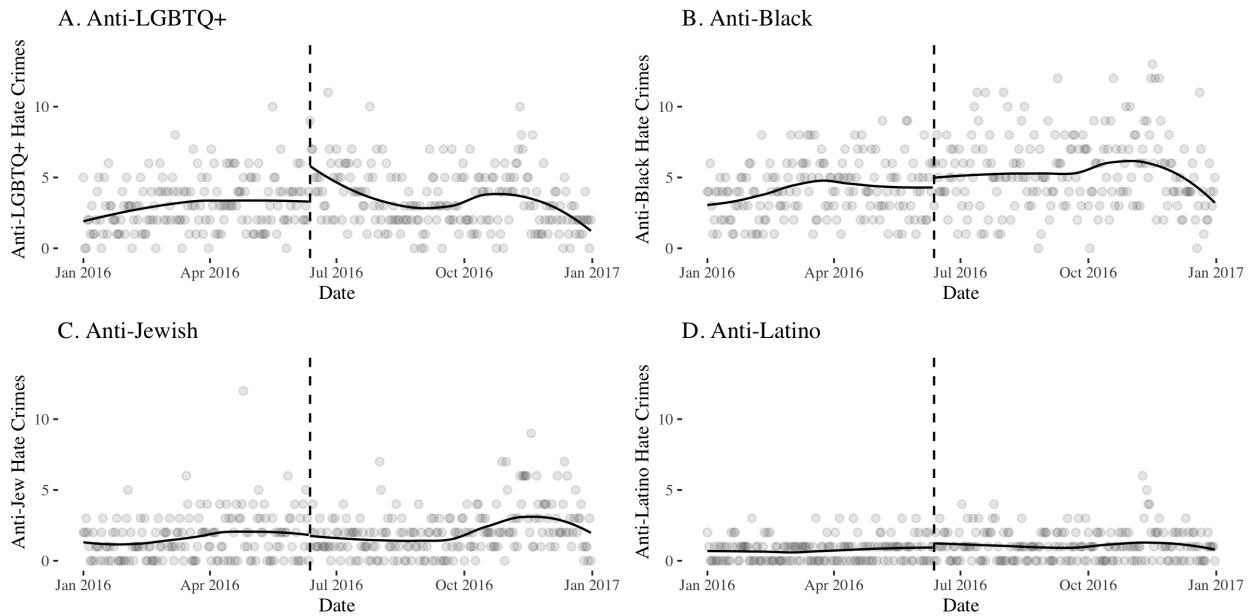

Figure A7: Descriptive Statistics Characterizing Different Hate Crimes Over Time in 2016. The x-axis is the date. The y-axis is the number of hate crimes in a given day. Dashed vertical line denotes the moment the Pulse massacre occurred (June 12). Loess lines fit on each side of the moment the Pulse massacre occurred. Panels A-D display anti-LGBTQ+, anti-Black, anti-Jewish, and anti-Latino hate crimes.

A.11.3 Anti-LGBTQ+ Hate Crimes: RDiT Estimates

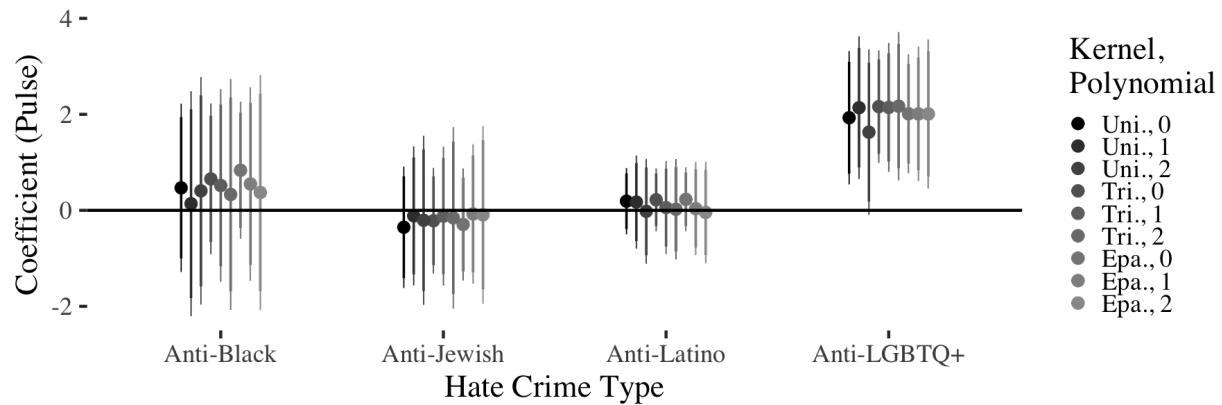

Figure A8: Regression Discontinuity-in-Time *Post-Pulse* Coefficient Estimates and Hate Crimes The x-axis is the hate crime type. The y-axis is the *Post-Pulse* coefficient. Color denotes kernel and polynomial degree at use. 95% CIs displayed from robust standard errors.

A.11.4 Anti-LGBTQ+ Hate Crimes: Close to Bandwidth Estimates

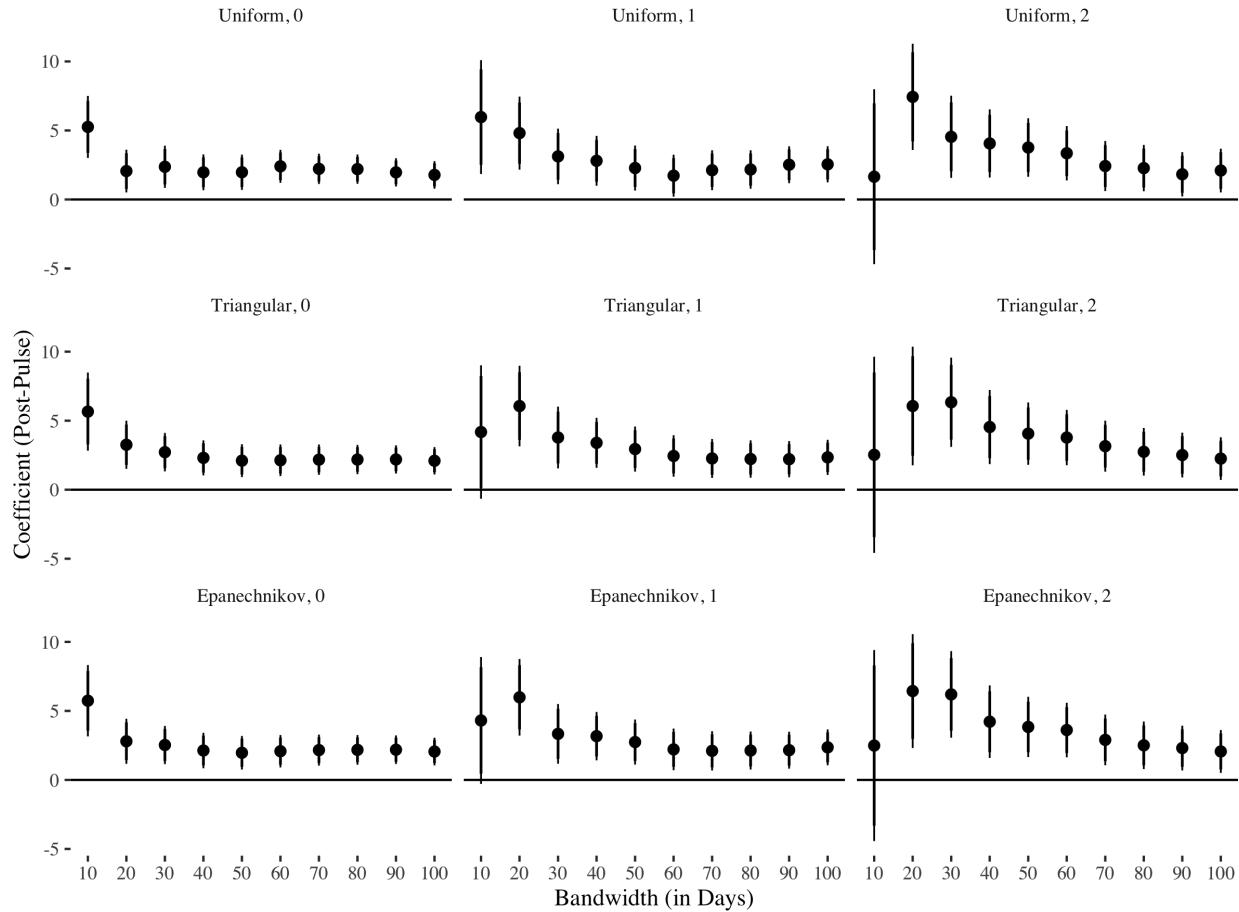

Figure A9: Regression Discontinuity-in-Time *Post-Pulse* Coefficient Estimates Using Bandwidths Close to Discontinuity The x-axis is the bandwidth (in days). The y-axis is the *Post-Pulse* coefficient. Each panel denotes the kernel at use and running variable polynomial degree (0-2). 95% CIs displayed from robust standard errors.

A.11.5 Anti-LGBTQ+ Hate Crimes: Pre-Pulse Temporal Placebo

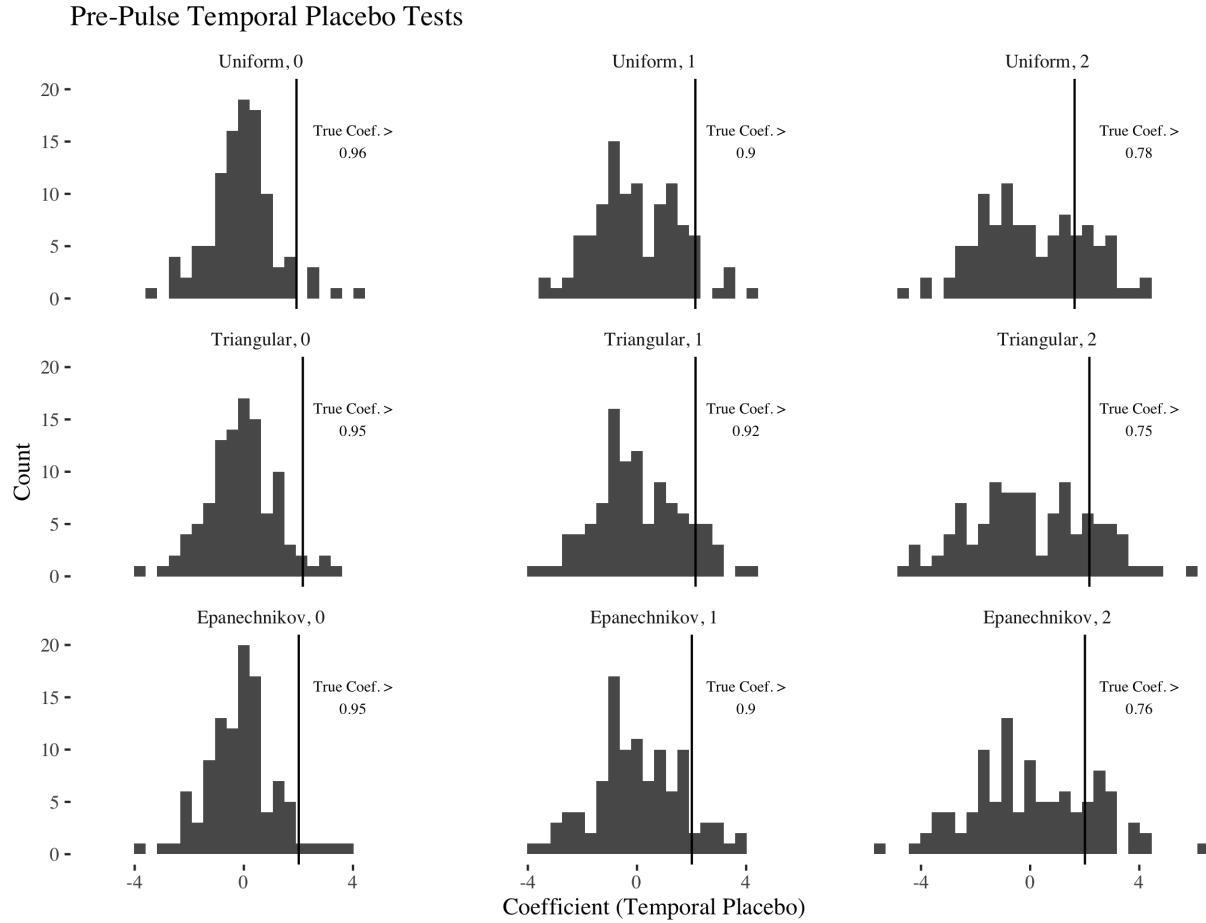

Figure A10: Comparing *Post-Pulse* Coefficient with Temporal Placebo Tests Prior to Pulse The x-axis is the temporal placebo coefficient size. Vertical line denotes true *post-Pulse* coefficient size. Annotation denotes the proportion of placebo coefficients the true coefficient is larger than. Panels denote kernel and polynomial degrees (0-2). 95% CIs displayed from robust standard errors.

A.11.6 Anti-LGBTQ+ Hate Crimes: Other Year Temporal Placebo

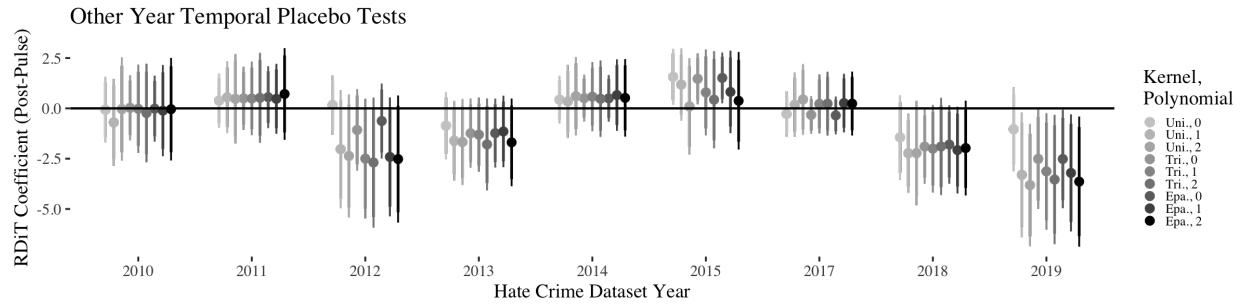

Figure A11: Post-June 12 Placebo Tests on Years Prior to and After Pulse. The x-axis denotes the hate crime dataset year (2010-2015, 2017-2019). The y-axis characterizes the RDiT coefficient of a placebo indicator equal to 1 after June 12, the calendar date of the Pulse massacre. Color denotes kernel and polynomial degree at use (0-2). 95% CIs displayed from robust standard errors.

A.11.7 Donations to Pro-LGBTQ+ Organizations

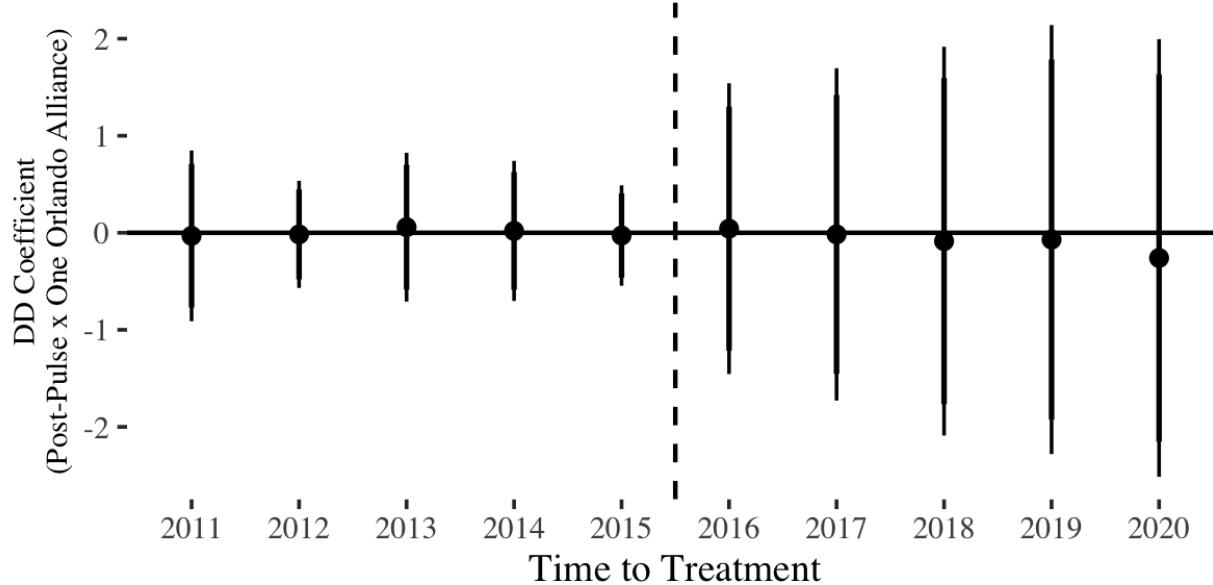

Figure A12: The Pulse Massacre Did Not Motivate A Differential Increase in Donations to Pro-LGBTQ+ Organizations in Florida. The y-axis is the differential effect of Pulse on the logged donations to Florida pro-LGBTQ+ organizations that are a part of the One Orlando Alliance. The x-axis is the time to treatment (tax years 2011-2020). Dashed line denotes *post-Pulse* coefficients. 95% CIs displayed.

To assess if the Pulse massacre motivated support for pro-LGBTQ+ organizations serving the Orlando LGBTQ+ community, we assess if contributions (i.e. donations) to non-profit pro-LGBTQ+ organizations serving Orlando differentially increased relative to other non-profit organizations after the Pulse massacre. We used two different datasets to conduct this assessment. First, we used tax return information on the universe of non-profits that submitted tax returns between 2011-2020 from the Internal Revenue Service (IRS).⁴⁰ This data includes our outcome of interest, the amount of monetary *contributions* declared in a given tax year (inflation adjusted to 2011 U.S. dollars). We log the contributions outcome (plus 1 to ensure identification, $\log(\text{contributions} + 1)$). Second, we merged this information with data we collected identifying non-profits who were serving the Orlando LGBTQ+ community and were soliciting monetary support through the One Orlando Alliance, a conglomerate of LGBTQ+ serving organizations in Central Florida that engaged in resource sharing after the Pulse massacre.⁴¹ Consistent with the sample we derived from the IRS data, we only included One Orlando organizations who filed tax returns for each year between 2011-2020 (suggesting they existed across the entire temporal domain of the panel) and were local, not national organizations (e.g. the Human Rights Campaign, ACLU). We exclude national or-

⁴⁰Source: <https://www.irs.gov/charities-non-profits/form-990-series-downloads>

⁴¹Source: <https://oneorlandoalliance.org/our-history/>

ganizations identified on the One Orlando Alliance member list from the IRS data as well.⁴² One Orlando Alliance non-profit organizations are coded 1 if they are a part of the Alliance and 0 otherwise in the IRS data (*alliance*).

Figure A12 displays event study estimates from a synthetic controls approach developed by Xu (2017) characterizing the differential effect of Pulse on One Orlando Alliance organization donation receipts. We use the synthetic controls approach to reweight pre-treatment outcome data from the set of untreated non-profit organizations to generate a counterfactual that satisfies the parallel trends assumption to derive the plausibly causal effect of Pulse on contributions to One Orlando Alliance organizations. The event study demonstrates the effect of Pulse on differential donations to Orlando LGBTQ+-serving organizations is 0, suggesting Pulse did not motivate an increase in donations or contributions to key Orlando LGBTQ+-serving organizations.

⁴²See <https://oneorlandoalliance.org/our-members/> for the complete list of One Orlando Alliance affiliated organizations, the organizations included in the sample are: 1) Community Legal Services of Mid Florida, 2) Equality Florida, 3) Family Equality, 4) Hope & Help, 5) Hope Community Center, 6) Legal Aid Society of the Orange County Bar Association, 7) Mental Health Organization of Central Florida, 8) Miracle of Love, 9) Orlando Gay Chorus, 10) Planned Parenthood of Southwest and Central Florida 11) Victim Service Center of Central Florida.

A.11.8 Blood Donations

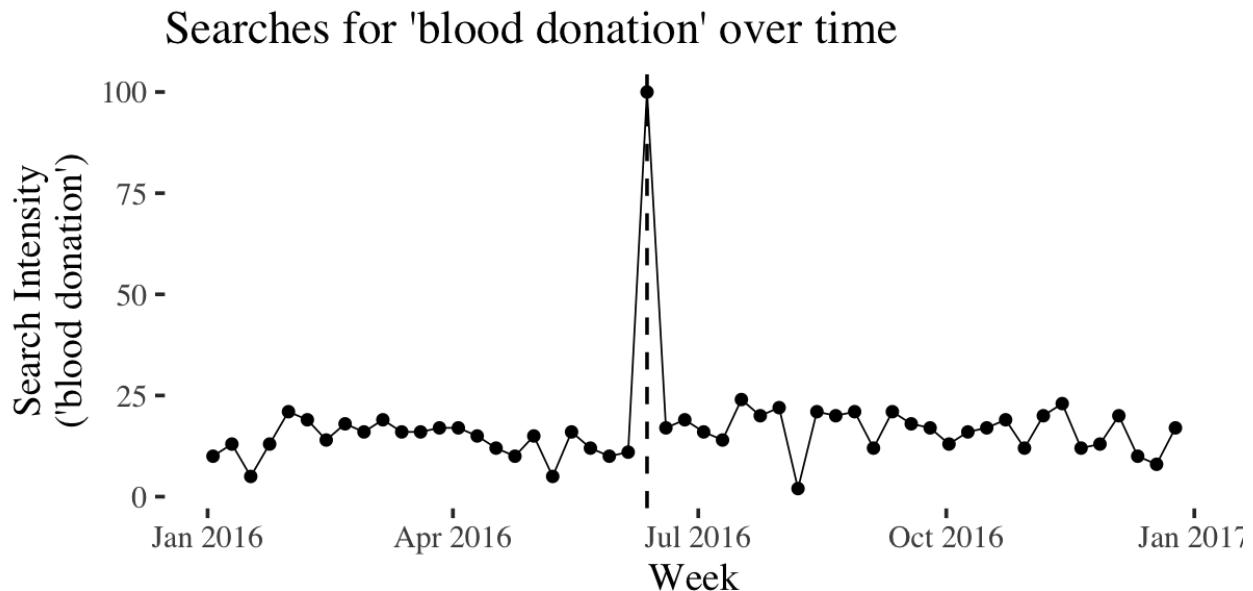

Figure A13: The Pulse Massacre Increased Search Interest in Donating Blood.

Given we do not possess direct data on blood donations for victims of the Pulse massacre, we use Google Trends data to identify the intensity of search interest in "blood donation" over time for the year 2016. Figure A13 clearly demonstrates search interest in "blood donation" substantially increases during the week of the Pulse massacre, but quickly drops off in the following weeks. Although search interest in "blood donation" may not necessarily translate into real-world behavioral action to donate blood, we are confident that our Google Trends analysis provides a rough proxy of real-world blood donation behavior due to qualitative accounts of blood donation after the Pulse massacre. According to the Orlando Sentinel,⁴³ Orlando hospitals who took in Pulse massacre victims "never had a shortage of blood and no victim experienced a delay in getting the right type of blood." This is because "Thousands of people began donating blood, throughout Florida and even in other states, starting hours after the June 12 shooting. The donations far exceeded the blood needed for the shooting." Moreover, "In the week after the attack, OneBlood took in 28,000 pints of blood; the agency's average weekly volume is about 18,000 pints...It was the biggest response since the Sept. 11 terror attacks in 2001."

The search intensity measure is the number of total searches concerning blood donations divided by the total searches of the geography (United States) and time range (January 1, 2016-December 31, 2016) it represents to compare relative popularity. The numbers are scaled on a range of 0-100 based on a topic's proportion to all searches on all topics. For more information see <https://support.google.com/trends/answer/4365533?hl=en>

A.12 Ruling Out Bundled Treatment Concerns With Placebo and Falsification Tests

One potential shortcoming of the two studies (Studies 1, 2) assessing the effects of *post-Pulse* on attitudes toward LGBTQ+ community segments is that the treatment is “bundled” in the sense that the Pulse massacre was perceived by the mass public as not only an anti-LGBTQ+ hate crime, but a terrorist attack in addition to an anti-Latino hate crime. Indeed, a plurality of the mass public perceived the shooting as *both* a terrorist attack and LGBTQ+ hate crime (Figure A5, Panel A). In addition, nearly 20% of the mass public perceived the shooting as a Latino hate crime (Figure A5, Panel B). Therefore, inconsistent with our theory, our findings may be driven by the fact the Pulse massacre was either a terrorist attack or anti-Latino hate crime.

We rule these possibilities out in several ways. First, we assess the effects of two prominent “Islamic” terrorist attacks on attitudes toward LGBTQ+ community segments: the April 2013 Boston bombing and the December 2015 San Bernardino shooting (Gunaratna and Haynal, 2013; Fitzpatrick, 2018). These incidents were highly salient to the mass public. Roughly 80% of the public reported they were following the Boston Bombing closely immediately after the bombing (higher than other salient issue at the moment of the bombing: the Gun Control Debate, Immigration Policy Debate, Texas Fertilizer Explosion, Poison Letters to Obama, Syrian Chemical Weapons, and Flight Delays, see Figure A15). The public also rated the San Bernardino attack the second most important issue or two of 2015, beating the Gay Marriage Decision, the Republican primary, and the Iran Deal (Figure A17). If pro-LGBTQ+ beliefs manifest after these terrorist attacks, then our findings may not be driven primarily by the perception of anti-LGBTQ+ violence, but rather the perception of a terrorist attack motivated by radical beliefs associated with Islam.

Figures A16 and A18 display coefficients characterizing the influence of the Boston bombing and the San Bernardino shooting on the *D-score*, *straight bias*, and *heterocentrism* outcomes using Project Implicit Sexuality IAT data from 2013 and 2015 respectively (5-50 day bandwidths from the moment of the event of interest).⁴⁴ With the exception of late-term effects for the *D-score* outcome in the 2015 data assessing the influence of the San Bernardino shooting, these events have had a null influence on the various outcomes of interest. Although the *D-score* appears to decrease after the San Bernardino shooting, *heterocentrism* does not decrease as well in a manner similar to the *post-Pulse* effects. Moreover, the *D-score* decreases 30 days from the San Bernardino shooting, as opposed to just 15 days from the Pulse shooting. Therefore, the results characterizing the effect of the San Bernardino shooting are more likely to be a function of unobserved secular temporal trends unrelated to the shooting relative to the results characterizing the effect of Pulse. In the aggregate, these findings imply the fact the Pulse massacre was a terrorist attack inspired by ISIS is not the main channel driving our results.

Second, we demonstrate that the effects are not motivated by negative attitudes toward Muslims/Islam in response to terror attacks associated with extremist Islamic organizations. For instance, the American mass public may seek to distinguish themselves from an

⁴⁴All outcomes for the Boston and San Bernardino attack analyses are measured similarly as those in the main text for Study 2. The Boston and San Bernardino attack analyses also adjust for the same covariates outlined in Study 2.

Islamic/Muslim ideology that is perceptibly socially conservative on the dimension of sexuality and/or queerness in response to terror attacks (i.e. “pinkwashing,” see Meyer (2020)). Consequently, the mass public may adopt prosocial beliefs toward segments of the LGBTQ+ community after the Pulse massacre as a function of concomitant animosity toward Muslims. If this mechanism explains our findings, then we may expect the mass public to adopt negative attitudes and/or behaviors toward Muslims and/or their political rights after the Pulse massacre.

We provide three pieces of evidence this mechanism may not be operative. Relative to respondents interviewed before Pulse, respondents interviewed after Pulse in the Project Implicit Arab IAT data do not adopt negative attitudes toward Arabs (Section C.8), an ethnic group strongly associated with Islam (d’Urso, 2022). In addition, we use two nationally representative ABC News telephone surveys fielded shortly before and after the Pulse massacre to demonstrate members of the mass public interviewed after the Pulse massacre are not more likely to support banning Muslims from entering the United States (i.e. the “Muslim Ban”, see Figure A21). Finally, we use day-level hate crime data from the FBI Uniform Crime Report between January 1, 2016-December 31, 2016 to assess if the Pulse massacre motivated anti-Muslim or anti-Arab hate crimes. Behaviorally, the mass public may engage in anti-Muslim or anti-Arab hate crimes in response to terror attacks associated with extremist Islamic/Muslim organizations (Welch, 2006). We assess the discontinuous effect of the Pulse massacre on the daily number of anti-Muslim/anti-Arab hate crimes, and find the Pulse massacre did not result in an increase in anti-Muslim/anti-Arab hate crimes (Figure A22).

These empirical findings suggest our results are not driven by a heightened animosity toward Muslims in response to terror attacks associated with Islam among the mass public. Instead, these findings provide further support for our claim that the mass public perceived the Pulse massacre as an instance of anti-LGBTQ+ violence, and adopted prosocial attitudes toward segments of the LGBTQ+ community accordingly, at least briefly.

Third, we assess the effect of a prominent anti-Latino hate crime on attitudes toward LGBTQ+ community segments: the August 2019 El Paso Shooting (Leander et al., 2020). According to Google Trends, this incident was the most prominent hate crime of 2019, with the exception of the Jussie Smollett debacle in January/February 2019 (Figure A19). Again, if pro-LGBTQ+ beliefs manifest after the 2019 El Paso shooting, then our findings may not be driven via the channel of anti-LGBTQ+ violence, but anti-Latino violence. To assess the influence of the El Paso Shooting on pro-LGBTQ+ beliefs, we use UCLA Nationscape data from the Democracy Fund Voter Study Group (5-50 day bandwidths from the El Paso shooting),⁴⁵ a large non-probability survey fielded each week by Lucid between July 2019-February 2021 weighted to national government population estimates.

The outcomes of interest in the Nationscape data are *LGBT unfavorability* (1 = “very unfavorable” or “somewhat unfavorable,” 0 = “somewhat favorable,” “very favorable,” or “haven’t heard enough”) and *no trans military* (1 = “disagree” to allowing transgender people to serve in the military,” 0 = “agree” or “not sure”). Therefore, negative coefficients characterizing being interviewed *after* the 2019 El Paso shooting suggest the mass public is adopting relatively positive attitudes toward LGBT people and the notion trans people may

⁴⁵See <https://www.voterstudygroup.org/data/nationscape> for details

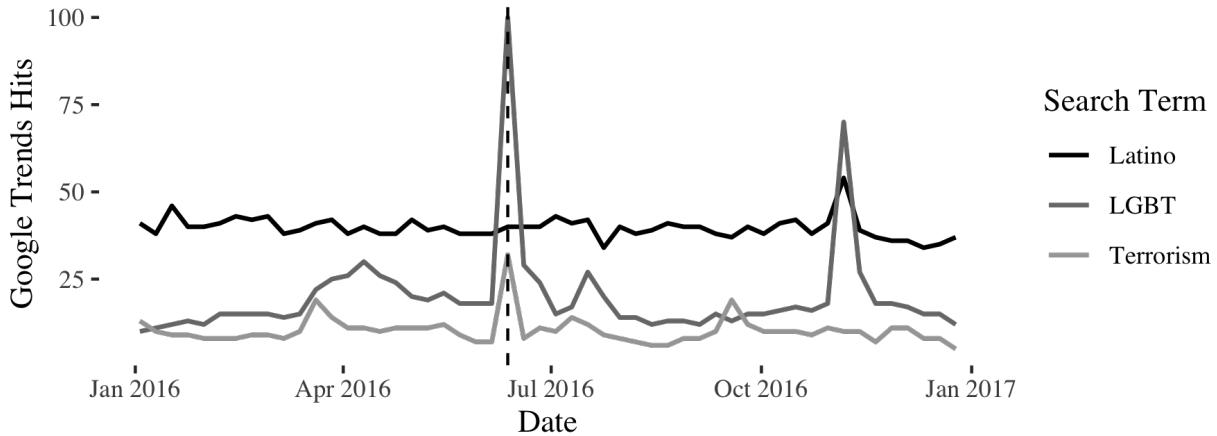

Figure A14: Google Search Intensity Across Different Search Terms. The x-axis is week. The y-axis is relative Google Search intensity between search terms for “LGBT,” “terrorism” and “latino”. Dashed vertical line denotes the moment of the Pulse massacre.

serve in the military.

For bandwidths between 5-50 days before and after the El Paso shooting, we do not find respondents interviewed after the shooting hold more favorable attitudes toward LGBT and the notion trans people may serve in the military (Figure A20). These findings imply the fact the Pulse massacre was an instance of violence against predominantly Latinx people is not the main channel driving our results. Instead, these findings suggest our main results assessing the effect of the Pulse massacre are driven by the perception the event was anti-LGBTQ+ violence.

Moreover, if the massacre motivated prosocial beliefs toward LGBTQ+ community segments because it was also an instance of violence against Latinxs, we may expect the massacre to motivate prosocial beliefs toward Latinxs. However, using an additional unexpected-event-during-survey design with the 2016 General Social Survey, we do not find that the massacre motivated reductions in old-fashioned ethno-racism toward Hispanics (Figure A24), a well-established measure of ethno-racism (Tesler, 2013). We also do not find the massacre increased support for a pathway to citizenship for undocumented immigrants in the TAPS survey (Figure 1, Panel C). A pathway to citizenship disproportionately benefits Latinxs given two-thirds of Latinxs are either immigrants or children of immigrants. These findings further suggest our results are driven by the fact the massacre was perceived as anti-LGBTQ+ violence, not anti-Latinx violence.

Additionally, we provide evidence that the mass public was particularly attentive to LGBT topics relative to issues related to terrorism or Latinos. Google Trends data shows that the relative search intensity for “lgbt” was much higher and pronounced the moment of the Pulse massacre than “terrorism” or “latino (Figure A14).” These findings further imply the Pulse massacre primarily motivated prosocial attitudes toward LGBTQ+ community segments through the perception of violence against LGBTQ+ people.

Lastly, our second context in the main text suggests bundled treatment considerations are moot (i.e. Matthew Shepard’s murder). Shepard’s murder was unequivocally under-

stood as an anti-gay hate crime by the mass public and political elites. Unlike Pulse, it was not simultaneously a terrorist attack or an instance of violence against Latinx people. Contemporary hate crime laws in the United States are even named after Matthew Shepard. Shepard's murder was not a terror attack nor an attack against a member of a politically non-dominant ethno-racial group. However, we find a similar pattern of results to the Pulse massacre, where positive attitudes toward gay people increase immediately after his murder, but dissipate in the long-run.

A.12.1 Terror Attack: Boston Bombing (2013)

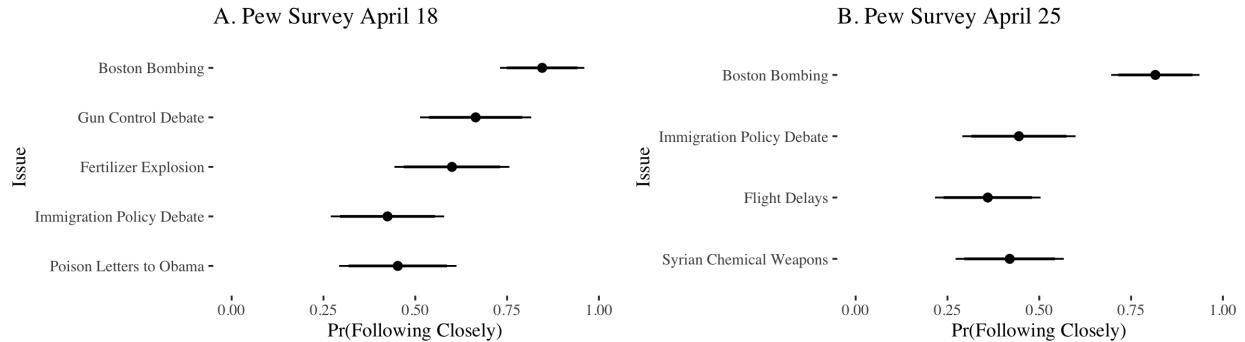

Figure A15: Salience of Boston Bombing. The x-axis is the proportion of respondents following each issue closely, the y-axis is the respective issue. Panel A is data from the April 18 Pew Survey. Panel B is data from the April 25 Pew Survey. 95% CIs displayed from 1000 bootstrap simulations. All estimates use survey population weights.

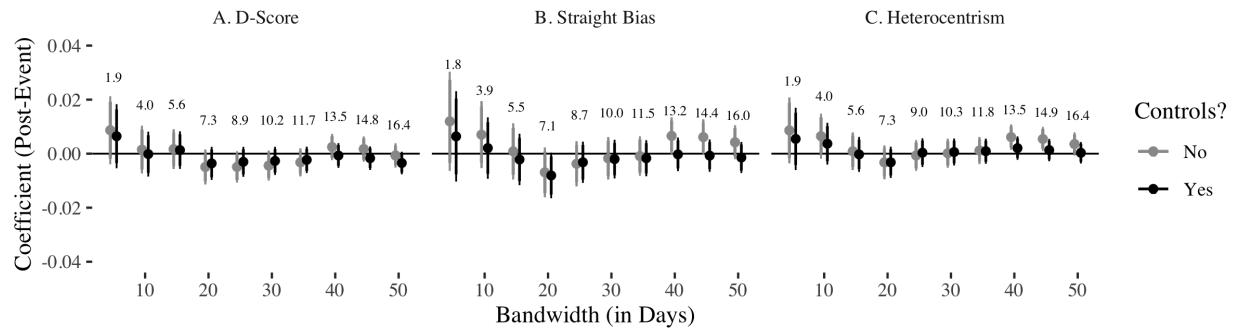

Figure A16: Influence of Boston Bombing on Anti-Gay Attitudes. The x-axis is the bandwidth (in days) used from the PI S-IAT data. The y-axis is the post-event coefficient. Annotations denote sample size (in thousands) corresponding to each respective coefficient estimate along the bandwidth size. All covariates rescaled between 0-1. 95% CIs displayed from HC2 robust standard errors.

A.12.2 Terror Attack: San Bernardino (2015)

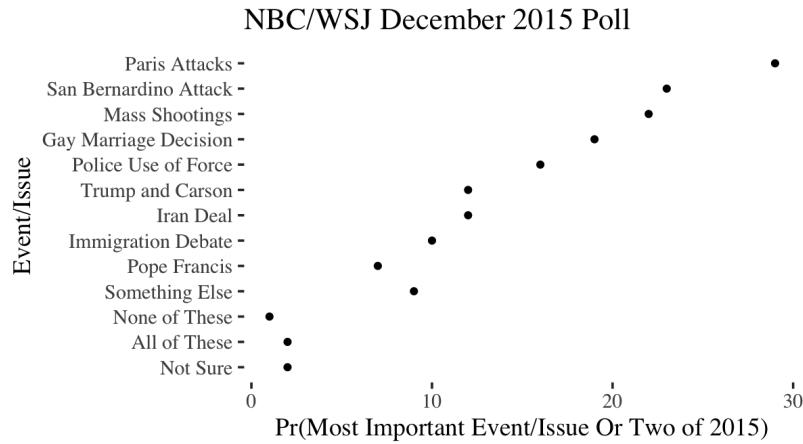

Figure A17: Salience of San Bernardino Shooting. The x-axis is the proportion of respondents indicating each issue was the most important (or two) of 2015, the y-axis is the respective issue. Data are from the NBC/Wall Street Journal December 2015 poll.

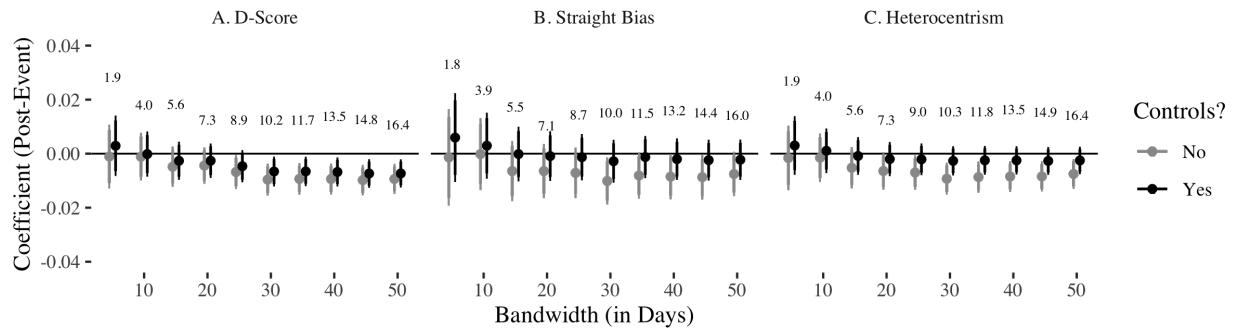

Figure A18: Influence of San Bernardino Shooting on Anti-Gay Attitudes. The x-axis is the bandwidth (in days) used from the PI S-IAT data. The y-axis is the post-event coefficient. Annotations denote sample size (in thousands) corresponding to each respective coefficient estimate along the bandwidth size. All covariates rescaled between 0-1. 95% CIs displayed from HC2 robust standard errors.

A.12.3 Anti-Latino Attack: El Paso (2019)

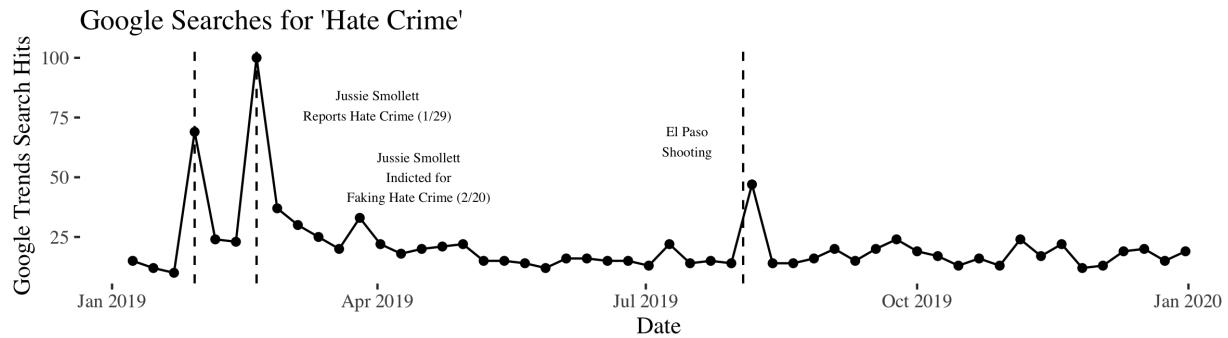

Figure A19: Salience of El Paso Shooting As A Hate Crime. The x-axis is the date (in weeks), the y-axis is the Google search hit intensity for “hate crime.” From left to right, dashed vertical lines denote Jussie Smollett reporting a hate crime, his indictment for faking the hate crime, and the El Paso shooting.

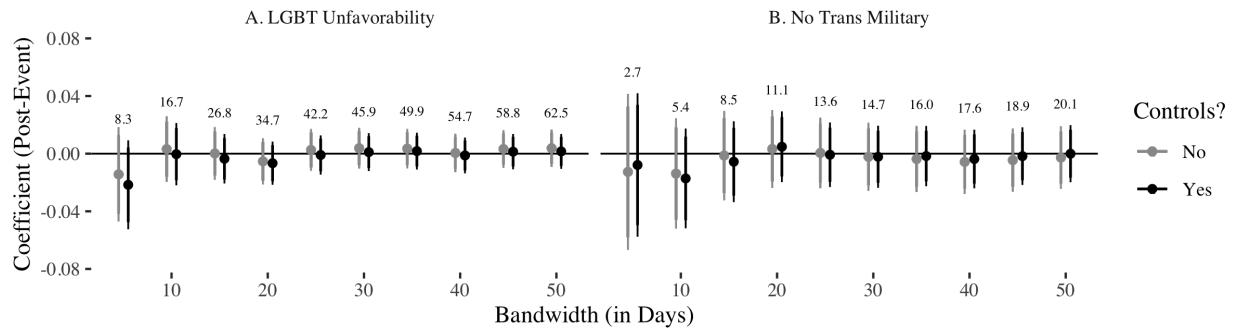

Figure A20: Influence of El Paso shooting on Anti-LGBTQ+ Attitudes. The x-axis is the bandwidth (in days) used from the Nationscape data. The y-axis is the post-event coefficient. Annotations denote sample size (in thousands) corresponding to each respective coefficient estimate along the bandwidth size. Differences in sample sizes across outcomes are not due to non-random missingness, but rather the random omission of the *no trans military* outcome item in the Nationscape data for respondents in the weekly subsamples. All covariates rescaled between 0-1. 95% CIs displayed from HC2 robust standard errors. All estimates use survey population weights.

A.12.4 Muslim Ban Falsification

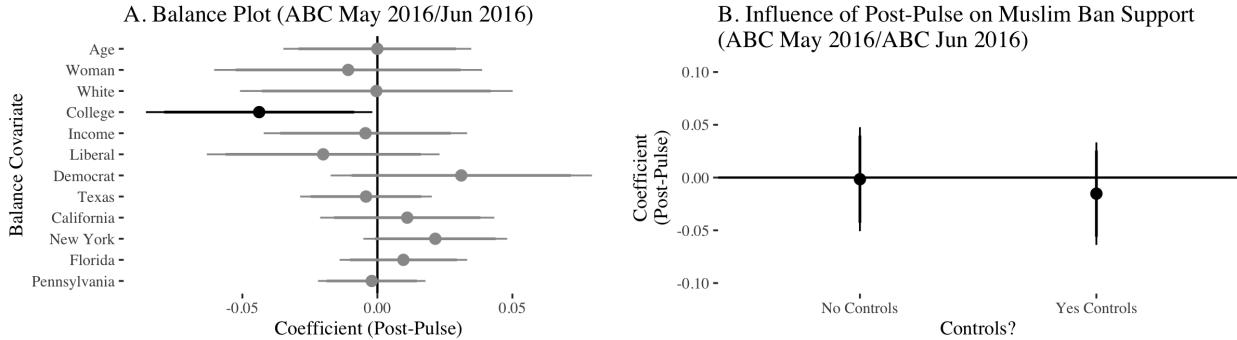

Figure A21: Influence of Pulse Massacre on Support for Muslim Ban. Panel A characterizes covariate balance between the ABC News May 2016 and ABC News June 2016 surveys. Panel B characterizes the influence of being interviewed in the June 2016 survey on support for the Muslim Ban with and without control covariates (i.e. the balance covariates). All covariates rescaled between 0-1. 95% CIs displayed from HC2 robust standard errors. All estimates use survey population weights.

Details: To assess the influence of Pulse on attitudes toward the Muslim Ban, we stacked two different ABC News Telephone Polls fielded shortly before and after the Pulse massacre. The first ABC survey was fielded between May 16-19, 2016 ($N = 1005$), less than one month before the massacre. The second ABC survey was fielded between June 20-23, 2016 ($N = 1001$), just a week after the massacre. The outcome of interest is support for the Muslim Ban. The two surveys ask respondents if they “would support or oppose a temporary ban on Muslims who are not U.S. citizens from entering the United States?” The outcome is coded 1 if the respondent indicates “support, strongly” or “support, somewhat,” 0 if the respondent indicates “oppose, somewhat” or “oppose, strongly.” We assess the effect of being interviewed *post-Pulse* relative to pre-Pulse. If respondents are inclined to restrict the rights of Muslims *post-Pulse*, then the *post-Pulse* coefficient with respect to the Muslim Ban outcome would be positive. We also adjust for a number of covariates (age, woman, white, college education, income, liberal ideology, Democrat, and state-level indicators for Texas, California, New York, Florida, and Pennsylvania), that we also assess balance for, suggesting that respondents interviewed before and after Pulse in the ABC polls are compositionally similar (Figure A21, Panel A). We do not find evidence respondents interviewed after Pulse are more likely to support the Muslim Ban (Figure A21, Panel B). With or without covariate adjustment, the post-Pulse coefficients being either 0 or near-zero, and statistically insignificant.

A.12.5 Muslim Hate Crime Falsification

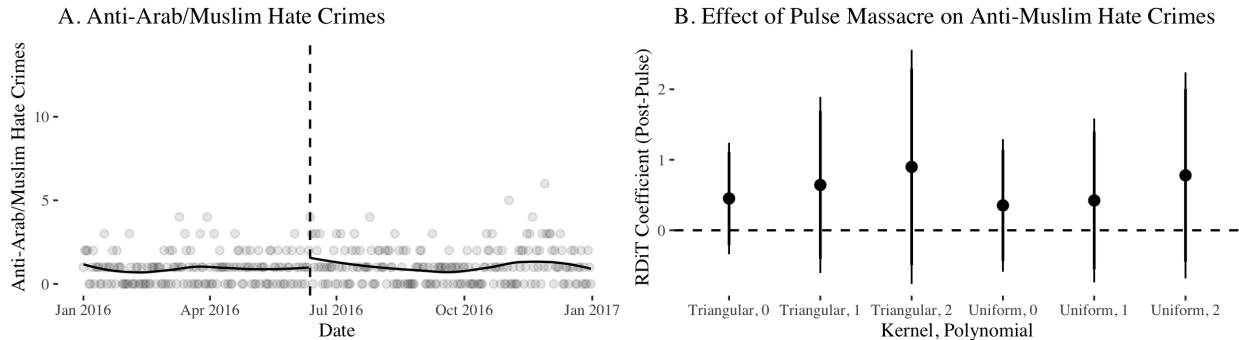

Figure A22: Discontinuous Effect of Pulse Massacre on Anti-Muslim/Anti-Arab Hate Crimes. Panel A characterizes daily anti-Muslim/Arab hate crimes over time in 2016. Solid lines are loess models fit to each side of the moment the Pulse massacre occurs. The dashed vertical line characterizes the moment the Pulse massacre occurs. Panel B characterizes regression discontinuity-in-time (RDiT) coefficient estimates (y-axis) of the effect of the Pulse massacre on anti-Muslim/Arab hate crimes across kernel/polynomial specifications (x-axis). Bandwidth selection is data-driven, mean-squared optimal (see Calonico et al. (2015)). 95% CIs displayed derived from robust SEs.

A.12.6 Latino Old-Fashioned Ethno-Racism: Balance Tests

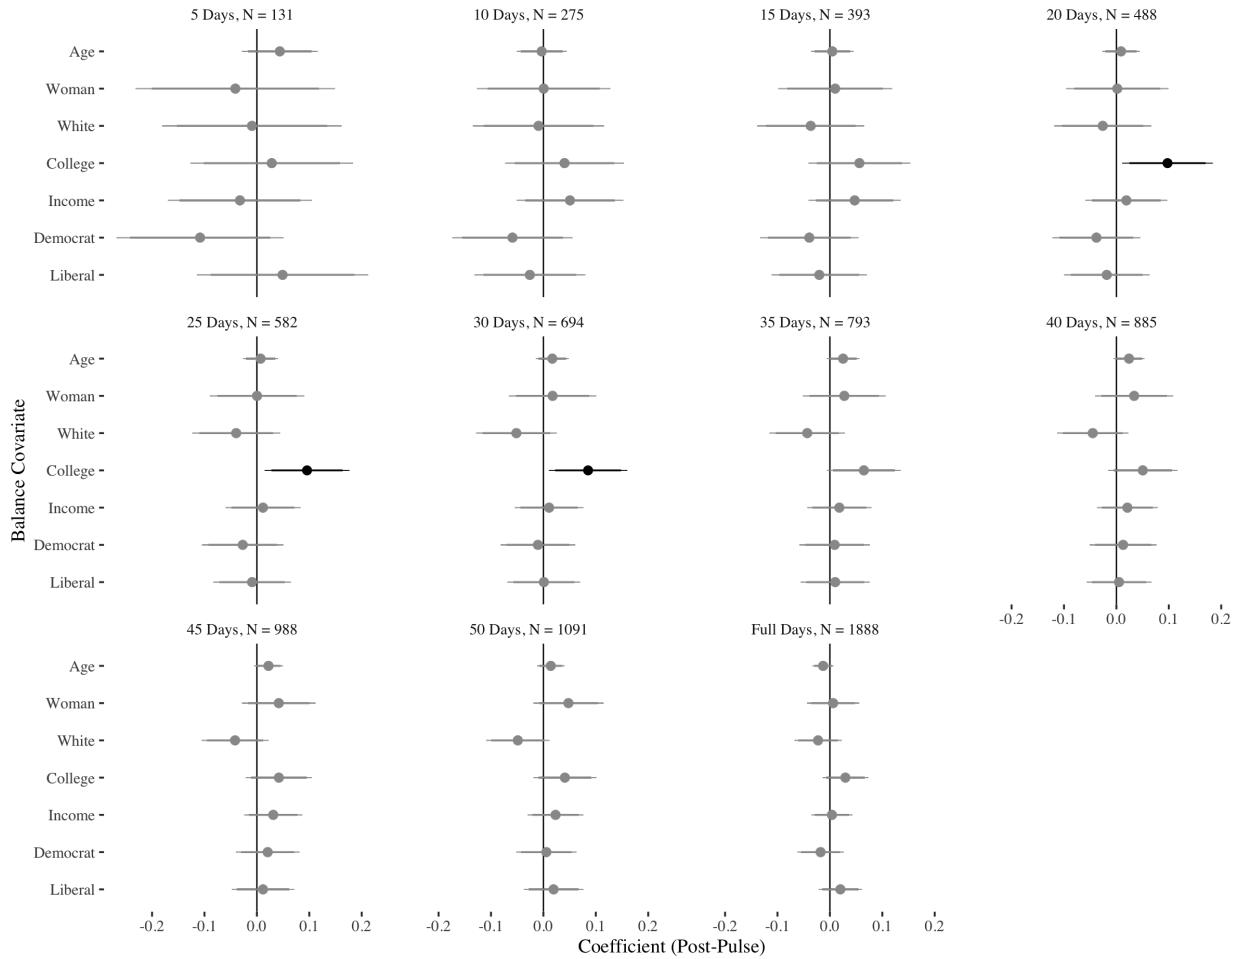

Figure A23: Balance Tests Between Respondents Interviewed Before and After the Pulse Massacre (GSS '16) The x-axis is the *post-Pulse* coefficient, the y-axis is the balance covariate. Each panel characterizes the bandwidth (5-50 days, then full sample) and sample size for each bandwidth sample. Black coefficients are statistically significant, grey otherwise. All estimates are population-weighted. Data is from the 2016 General Social Survey. 95% CIs displayed derived from robust SEs.

A.12.7 Latino Old-Fashioned Ethno-Racism: Effects of Pulse

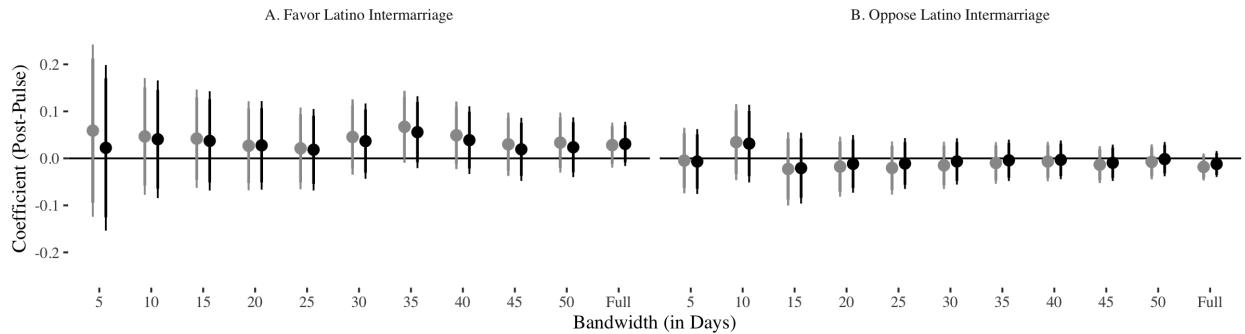

Figure A24: Effect of Pulse on Old Fashioned Ethno-Racism (GSS '16). The x-axis is the bandwidth sample at use (in days), the y-axis is the *post-Pulse* coefficient. The outcome for Panel A is a binary indicator if the respondent indicates they favor intermarriage with a Latino for a familial relative, the outcome for Panel B is a binary indicator if the respondent indicates they oppose intermarriage with a Latino for a familial relative. Black coefficients are from models adjusting for age, gender, race, college-education, income, partisanship, and ideology, grey otherwise. Data is from the 2016 General Social Survey. 95% CIs displayed derived from robust SEs.

B Study 1: TAPS

B.1 Outcome Measurement

To measure support for same-sex marriage, we use an item in the June 2016 TAPS survey asking respondents if “you generally support or oppose same-sex marriage.” with options to choose: 1) Support; 2) Oppose; and 3) No opinion.

B.2 Manipulation Check

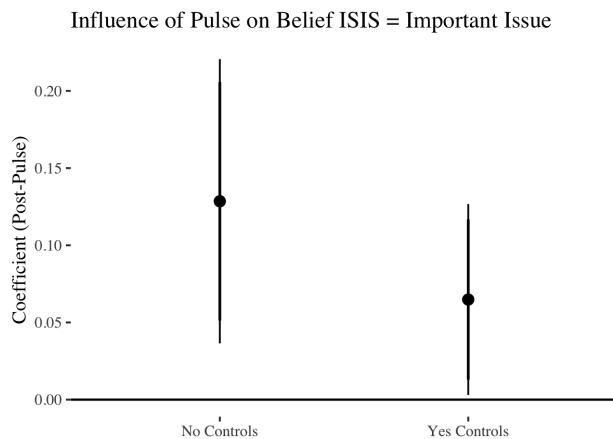

Figure B25: Belief ISIS = Most Important Issue Increases After Pulse. All estimates use post-stratification survey weights to ensure representativeness. All covariates scaled between 0-1. 95% CIs displayed derived from HC2 robust standard errors.

B.3 Insensitivity to Truncation

Table B2: Comparison Between truncated TAPS June '16 Sample and ANES '16 Sample

Covariate	TAPS Jun. '16	ANES '16	Diff.	T-test	p-value
Woman	0.51	0.51	0.01	0.73	
White	0.78	0.78	0.01	0.71	
Age (18-29)	0.20	0.18	0.03	0.03	
Age (30-44)	0.24	0.23	0.00	0.76	
Age (45-59)	0.29	0.32	-0.02	0.13	
Age (60+)	0.26	0.27	-0.01	0.55	
College	0.31	0.29	0.02	0.16	
Liberal	0.39	0.41	-0.02	0.32	
California	0.10	0.09	0.01	0.49	
New York	0.05	0.04	0.01	0.36	
Florida	0.05	0.06	-0.01	0.22	
Pennsylvania	0.05	0.05	-0.00	0.93	
Texas	0.07	0.08	-0.01	0.18	

Figure B26 displays estimates using different types of data truncation. The x-axis displays the kinds of respondents that are removed. For instance, $>15, <60$ means that respondents who took more than 15 minutes and less than 60 minutes are included in the sample, and those who took less than 15 minutes and more than 60 minutes are excluded from the sample.

The truncated estimates operate in a manner consistent with the notion that respondents who take the survey either too quickly or too slowly are less attentive. Respondents who take the survey too quickly may not have sufficient time to make cognitive connections between their political context and their expressed attitudes on particular issues. Respondents who take the survey for too long may be intermittently attentive to the survey or are not taking the survey as seriously as they otherwise should, again, undercutting cognitive connections between their political context and their expressed attitudes on particular issues (Malhotra, 2008; Read et al., 2021). We find that removing respondents who take too long to take the survey increases the size of the coefficient estimates, consistent with research on how inattention attenuates coefficient estimates. However, we do not find that removing speeders increases the size of the coefficient estimates (for example, respondents who take less than 15 minutes to take the survey, the threshold we use for the results in the main text).

We do not believe this to be a problem, given *most speeders are not engaging in egregious levels of speeding* and true speeders are a *very small proportion of the sample*, which would suggest speeders have an inconsequential effect on coefficient size. In the TAPS data, of the speeding population (that is, those who take the survey in less than 15 minutes), over 80% take the survey in more than 10 minutes. This is fast for a large survey, but not egregiously fast. The other 20% (only 21 respondents), took the survey in less than 10 minutes. Therefore, the number of serious speeders may not be large enough to affect *post-Pulse* coefficient estimates. But, dropping slow respondents based on our cutoff leads to 352 dropped respondents, who may be particularly inattentive to the survey given that the median “slow respondent” took 1421 minutes (24 hours) to respond to the survey.

Regardless, the results are *insensitive to truncation*. Across the different truncated estimates adjusting for controls on Figure B26, 15/16 are statistically significant at $p < 0.10$,

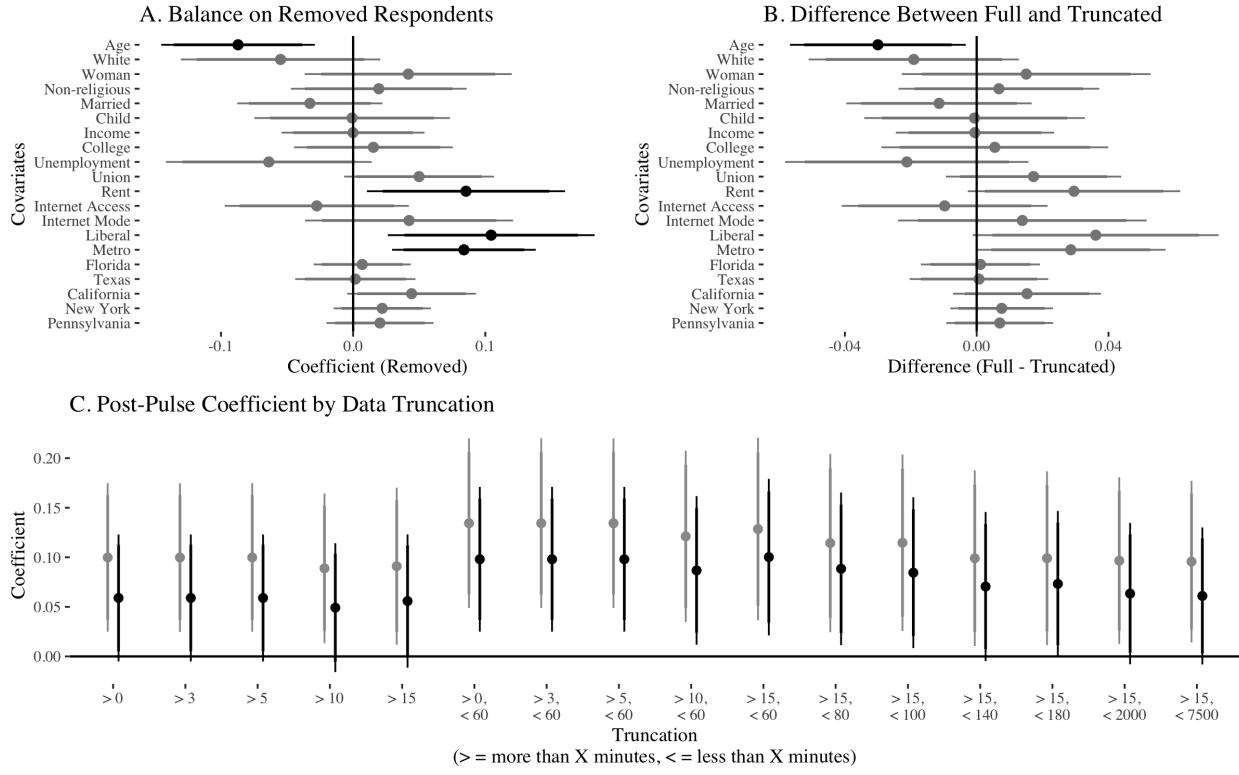

Figure B26: Truncated Estimates. Panel A displays balance between removed respondents (who finished the survey in less than 15 minutes, more than 60) and respondents that were not removed. Panel B displays balance between the full and the truncated sample. Panel C displays coefficients characterizing the influence of *post-Pulse* on *SSM support* based on various samples removing respondents who took more than or less than a particular number of minutes (defined on the x-axis). For Panels A-B, black coefficients are statistically significant, grey otherwise. For Panel C, black coefficients are derived from regression models including baseline control covariates (i.e. the balance covariates), grey coefficients are derived from regression modeels that do not include control covariates.

and 8/16 are statistically significant at $p < 0.05$. Importantly, the results hold without truncating the data at all at $p < 0.10$ (Figure B26, Panel C). The findings on temporal persistence are also the same without truncating the data (Figure B27). In addition, the *post-Pulse* effect may not be biased given the TAPS survey, when weighted, is compositionally similar to the 2016 ANES, the gold standard in representative surveys. Prior evidence suggests the maintenance of a representative sample composition mitigates the prospect for coefficient effect bias after truncating data to attentive respondents (Alvarez et al., 2019).

Moreover, one might think the larger effects sizes we derive using the truncated sample may be due to cognitive difficulties or lifestyle factors. The one difference between the truncated and full sample is that the truncated sample includes *less* youth. Prior work shows younger people are less attentive (Alvarez et al., 2019), but they also tend to be more pro-LGBTQ+, so that should ostensibly attenuate effect estimates from a substantive basis but increase effect estimates from the basis of increasing attention. Likewise, if the problem

The Influence of Pulse on SSM Support Attenuates Over Time

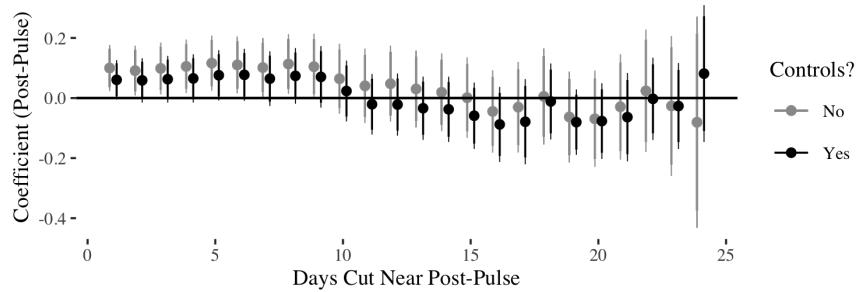

Figure B27: The Influence of Pulse on SSM Support Attenuates Over Time (Using Full TAPS Sample).

was cognition, then the truncated sample, which is older, should have smaller effects, given older people tend to be more likely to experience cognitive decline (Murman, 2015). We do not observe smaller effects using the older, truncated sample, suggesting cognitive decline may not bias our coefficient estimates. Therefore, we feel confident our truncation exercise is removing respondents inattentive to survey content.

B.4 Baseline Covariate Measurement

Age is a 4 category index from 0-3 characterizing respondents aged 18-29, 30-44, 45-59, 60+. Scaled between 0-1.

White is a binary indicator equal to 1 if the respondent indicates that “white” is a race they currently identify as.

Woman is a binary indicator equal to 1 if the respondent indicates they are “female” in response to a question asking if they are female or male.

Child is a binary indicator equal to 1 if the respondent indicates they have children in response to an item asking if they have biological or adopted children.

Non-religious is a binary indicator equal to 1 if the respondent indicates they are “not religious” in response to an item asking if they consider themselves Christian, Jewish, Muslim, Buddhist, Hindu, or another religion.

Married is a binary indicator equal to 1 if the respondent did not indicate they were divorced, widowed, separated from their partner, or never married.

Income is a 0-5 scale of the respondents self-reported household income from < \$10,000, \$10-29,999, \$30-49,999, \$50-79,999, \$80-99,999, \$100,000 or more. Scaled between 0-1.

College is a binary indicator equal to 1 if the respondent reports the highest level of school they have completed is at or above a bachelor’s degree.

Unemployment is a binary indicator equal to 1 if the respondent reports they are not working at a job for pay.

Union is a binary indicator equal to 1 if the respondent reports they or someone in their household is a member of a labor union.

Rent is a binary indicator equal to 1 if the respondent reports they rent when asked if they rent or own their home.

Internet Access is a binary indicator equal to 1 if the respondent reports they have household internet access.

Internet Mode is a binary indicator equal to 1 if the respondent was recruited via an online mechanism instead of mail, call-in, or outbound calls.

Liberal is a binary indicator equal to 1 if the respondent indicates they are “slightly liberal,” “liberal,” or “very liberal” in addition to indicating that they are “liberal if they had to choose” in an additional question conditional on indicating “don’t know” or “moderate” in the initial question.

Metro is a binary indicator equal to 1 if the respondent lives in a zipcode that is a metropolitan area.

State indicators (Florida, Texas, California, New York, Pennsylvania) are equal to 1 if the respondent self-reports they live in the respective states.

B.5 SSM Support By Interview Date

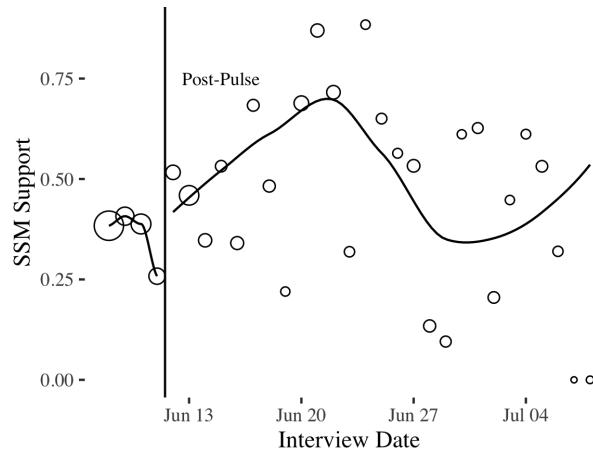

Figure B28: Support for Same Sex Marriage (y-axis) Across Interview Dates (x-axis). Vertical line is the moment the Pulse nightclub shooting occurred. Loess models are fit on each side of the moment the Pulse shooting occurred and are weighted based on the interview date sample size. Larger circles denote more interviews on a given date. All covariates re-scaled between 0-1.

B.6 Outcome Item Non-response Balance

Table B3: Outcome Item Non-response is Balanced Between Pre and Post-Pulse Periods

SSM Item Non-Response

B.9 Temporal Placebo Tests

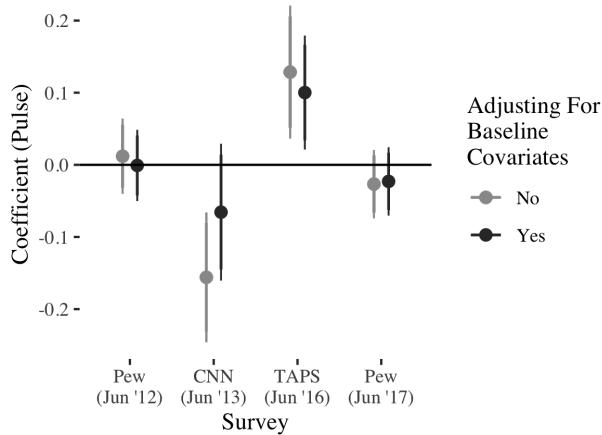

Figure B29: The Effect of Pulse is Unique to 2016. The x-axis is the survey at use. The y-axis is the coefficient for a binary indicator if the respondent was interviewed the calendar day after the Pulse massacre in 2012, 2013, 2016, and 2017 respectively. The outcome for all studies/models is support for same sex marriage. Color denotes the inclusion/exclusion of adjustment for baseline covariates between respondents interviewed before and after the calendar day of the Pulse massacre. All covariates rescaled between 0-1. 95% CIs displayed from HC2 robust standard errors.

B.9.1 Temporal Placebo Test Survey Information

Pew 2012: The 2012 Pew Voter Attitude Survey obtained telephone interviews with a nationally representative sample of $N = 2013$ adults living in the United States. The interviews were conducted by Princeton Survey Research Associates International between June 7, 2012 to June 17, 2012. The margin of sampling error for the complete set of weighted data is ± 2.6 percentage points. The same sex marriage outcome asks respondents if they

“strongly favor, favor, oppose or strongly oppose allowing gays and lesbians to marry legally.” The outcome is coded 1 if the respondent indicates strongly favor or favor, 0 otherwise.

CNN 2013: The 2013 CNN poll is a nationally representative survey using landline and cell phone sampling ($N = 1014$). The poll was in the field between June 11, 2013 and June 13, 2013. The same sex marriage outcome asks respondents if they “think marriages between gay and lesbian couples should or should not be recognized by the law as valid, with the same rights as traditional marriages?” The outcome is coded 1 if the respondent indicates gay and lesbian couples should be recognized by the law, and 0 otherwise.

Pew 2017: The 2017 Pew Political Landscape Survey was in the field between June 8, 2017 and June 18, 2017. It is a nationally representative survey of 2504 respondents. Interviews were conducted via landline and cell phone. The survey was conducted by Princeton Survey Research Associates International. The margin of error is ± 1.6 percentage points. The same sex marriage outcome asks respondents if they “strongly favor, favor, oppose or strongly oppose allowing gays and lesbians to marry legally.” The outcome is coded 1 if the respondent indicates strongly favor or favor, 0 otherwise.

B.10 Alternative Bandwidths

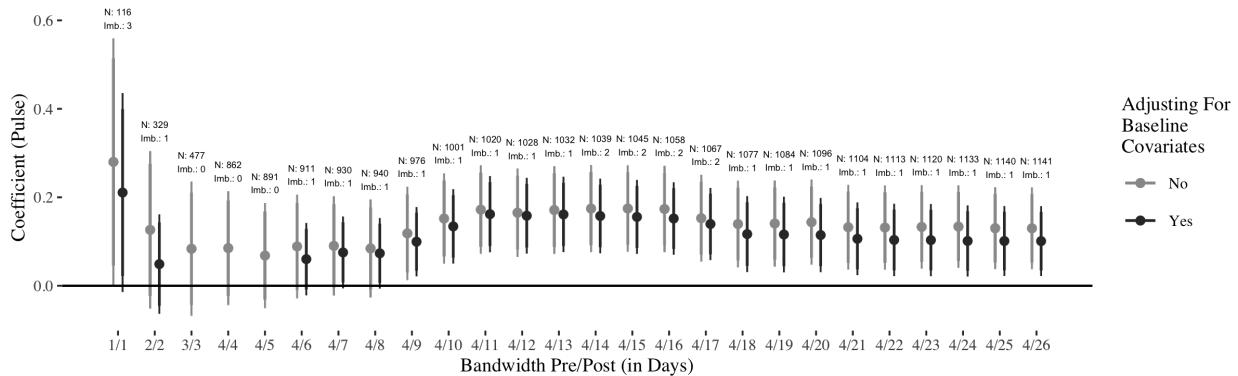

Figure B30: The Effect of Pulse is Robust to Alternate Bandwidths. The x-axis is the bandwidth (in days) for the pre and post Pulse period. The y-axis is the coefficient for a binary indicator if the respondent was interviewed after the Pulse nightclub shooting. Color denotes the inclusion/exclusion of control covariates adjusting for covariate imbalance between respondents interviewed before and after the Pulse nightclub shooting. Annotations denote sample size for each estimate in addition to the number of imbalanced covariates. All covariates re-scaled between 0-1. 95% CIs displayed from HC2 robust standard errors.

B.11 Ordinal Outcome Re-estimation

Table B13: Findings Are Robust To Using Ordinal Outcome

	SSM Support (Ordinal)

Post-Pulse x % LGBTQ (State)				-0.02 (0.77)				
Post-Pulse x SS Couple Density					-0.20 (0.34)			
Post-Pulse x Political Interest						0.03 (0.08)		
Post-Pulse x News Freq.							-0.02 (0.08)	
Post-Pulse x Liberal								0.01 (0.08)
R ²	0.37	0.36	0.36	0.36	0.36	0.36	0.36	0.35
N	1132	1132	1132	1132	1132	1132	1132	1132

Note: *** $p < 0.001$, ** $p < 0.01$, * $p < 0.05$. All models are fully specified, this table only presents the interaction between the *post-pulse* indicator and mechanisms that may explain the adoption of SSM support. HC2 robust standard errors in parentheses. SEs in Models 4, 5 are clustered at the state and county-level respectively. All variables are scaled between 0-1. All estimates are population-weighted.

B.14 Heterogeneity By Political Interest and Media Consumption

B.14.1 Measurement of Political Interest and Media Consumption

Political Interest: How interested would you say you are in politics and current affairs? 1) very interested, 2) somewhat interested, 3) not very interested, 4) not at all interested. Coded as a binary indicator equal to 1 if respondent puts “very interested,” 0 otherwise (45% say “very interested,” 55% say otherwise).

News Consumption: How frequently do you pay attention to news about national and international issues? 1) every day, 2) several times a week, 3) once a week, 4) several times a month, 5) once a month, 6) less often, 7) never. Coded as a binary indicator equal to 1 if respondent puts “every day,” 0 otherwise (59% say “every day”, 41% say otherwise).

Interest Scale: The *interest scale* is an additive index from 0-2 of the news consumption and *political interest* measures discussed above (0 = 32% of the sample, 1 = 32% of the sample, 2 = 36% of the sample).

B.14.2 Results

Table B16: Evaluating Heterogenous Influence of Post-Pulse Conditional on Political Interest and News Consumption

	SSM Support					
	(1)	(2)	(3)	(4)	(5)	(6)
Post-Pulse x Political Interest	0.00 (0.09)	0.03 (0.08)				
Post-Pulse x News Consumption			-0.11 (0.09)	-0.02 (0.08)		
Post-Pulse x Interest Scale					-0.04 (0.06)	0.00 (0.05)
Controls	N	Y	N	Y	N	Y
R ²	0.02	0.36	0.03	0.36	0.02	0.36
Num. obs.	1134	1132	1134	1132	1134	1132

Note: *** $p < 0.001$, ** $p < 0.01$, * $p < 0.05$. Models alternate between excluding/including control covariates. This table only presents the interaction between the *post-pulse* indicator and *political interest*, *news consumption*, and the *interest scale*. HC2 robust standard errors in parentheses. All covariates are scaled between 0-1. All estimates are population-weighted.

Here we assess the heterogenous influence of being interviewed *post-Pulse* on *SSM support* among TAPS respondents conditional on political interest and news consumption. We conduct this test to assess if those who are attuned to media and politics are differentially more likely to support the rights of segments of the LGBTQ+ community in response to exposure to violence against LGBTQ+ (Reny and Newman, 2021).

Table B16 demonstrates that the influence of being interviewed *post-Pulse* on *SSM support* is not heterogeneous with respect to *political interest*, *news consumption* levels, or the *interest scale*.

We do not think the absence of heterogeneity poses a problem for the validity of our results. Consistent with prior research, the *political interest* and *news consumption* measures capture a *general* disposition towards consuming media and politics that is relatively stable (Prior, 2010). But that general disposition may be abrogated in the context of high-salience events. This is to say, even those segments of the mass public who do not necessarily pay attention to salient political/media events may have internalized information about the Pulse massacre. This is corroborated by our evidence on Figure A1, which demonstrates that 86% (Kaiser Poll, June 15-21, 2016) to 89% (CBS News Poll, June 13-14, 2016) of the mass public was closely following the shooting. Therefore, nearly all of the mass public was closely following the Pulse massacre, implying high levels of potential treatment reception regardless of one's generalized *political interest* or level of *news consumption*.

B.15 Balance Tests After Removing Days After Pulse Event

C Study 2: PI S-IAT

C.1 Baseline Covariate Measurement

Age: Self-reported age, rescaled between 0-1.

Woman: 1 if respondent indicates they are “female,” 0 otherwise.

White: 1 if respondent indicates they are “white,” 0 otherwise.

College: 1 if respondent indicates the highest level of education they have is a “bachelor’s degree,” “some graduate school,” a “master’s degree,” a “J.D.,” a “M.D.,” a “PhD,” an other “advanced degree” or a “M.B.A.” 0 otherwise.

Liberal: 1 if respondent indicates their political identity is “slightly liberal,” “moderately liberal,” or “strongly liberal.” 0 otherwise.

Religious: 1 if respondent indicates they are not “not at all religious,” 0 otherwise

Non-Metro: 1 if respondent is not from a “nonmetropolitan area,” 0 otherwise.

California/Pennsylvania/New York/Florida/Illinois: 1 if respondent indicates their state of residence is California/Pennsylvania/New York/Florida/Illinois, 0 otherwise.

C.2 D-Score Details

The S-IAT acquires respondents mean *compatible response latency* (CRL) and *incompatible response latency* (IRL) (in milliseconds). The CRL is an average of how quickly a respondent associates “good” (e.g. happy, terrific) and “bad” (e.g. evil, rotten) words in addition to “gay” (e.g. homosexual, woman/woman image) or “straight” (e.g. heterosexual, man/woman image) words/images to a left or right-sided bin that characterize associations designed to be easy for people who prefer straight to gay people (e.g. gay/bad, straight/good). The IRL measures the same thing but where the left or right-sided bins characterize associations designed to be difficult for people who prefer straight to gay people (e.g. gay/good, straight/bad). The S-IAT assumes implicitly biased respondents will be faster making congruent than incongruent associations. Consequently, the *D-score* is the $IRL - CRL$ difference divided by the within-individual standard deviation of response latencies calculated across the compatible and incompatible trials. The *D-score* ranges from -2-2, with higher values suggesting implicit bias against gay people .

C.3 Anti-Gay Attitudes Over Time

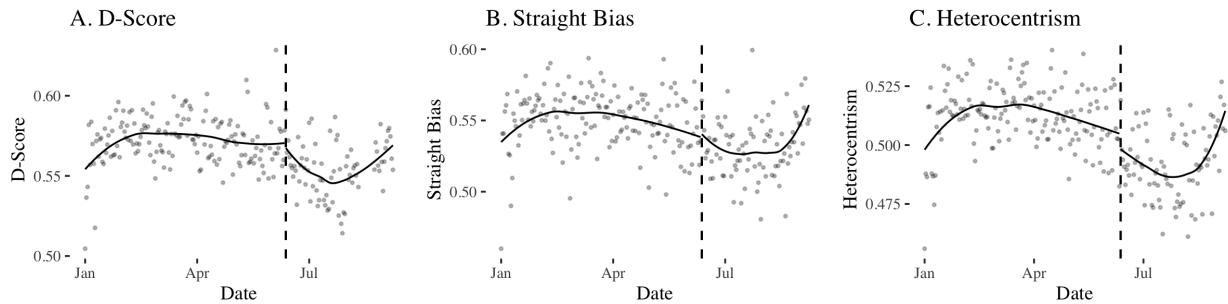

Figure C31: Anti-Gay Attitudes (y-axis) Over Time (x-axis, in days) Between 2016-01-01 and 2016-09-07. Dashed vertical line is the moment the Pulse nightclub massacre occurred. Loess models are fit on each side of the moment Pulse occurred. All covariates re-scaled between 0-1.

C.4 Explaining Coefficients = Meaningful

Figure 4 displays *post-Pulse* intent-to-treat coefficients where the outcome is the daily *D-score*, *straight bias*, and *heterocentrism*. Honing in on 15 and 20-day sample bandwidth estimates, respondents surveyed *post-Pulse* have a lower *D-score* (-0.01, $p < 0.10$) and *heterocentrism* (-0.01, $p < 0.01$), equivalent to roughly 7% and 8% of the respective outcome standard deviations pre-Pulse. Although these coefficients are small, they are reasonable and likely underestimated. First, prior research shows affective attitudes toward marginalized groups tend to be stable, so small attitudinal shifts may be meaningful (Sears, 1993; Vuletich and Payne, 2019). Second, the *D-score* is indirectly measured, so it is less subject to impression management. Thus, small coefficients may be meaningful because the mass public may have difficulties shifting automatic attitudes toward LGBTQ+ community segments. Third, conversely, *heterocentrism* is an explicit outcome asking respondents to indicate they favor straight to gay people. Thus, the measure may be subject to impression management where individuals who would otherwise adopt genuinely more prosocial beliefs toward LGBTQ+ group members may already be self-reporting disingenuous prosocial beliefs prior to the massacre on the basis of social desirability. These dynamics may generate ceiling effects on external stimuli that would otherwise motivate prosocial attitudes. Fourth, coefficients may be smaller since we are estimating an intent-to-treat effect with a relatively youthful PI S-IAT sample relative to TAPS in Study 1. Youth pay less attention to media (Neundorf et al., 2013). Therefore, they may be less likely to shift their attitudes in response to media context changes, which could attenuate ITT effects. Fifth, we cannot truncate to attentive respondents in Study 2 like Study 1 due to the absence of auxiliary interview length data.⁴⁶ Inattentiveness may produce underestimates of the *post-Pulse* coefficient. Finally, the coefficients are still meaningful from a relative basis. The *post-Pulse* coefficients for the *D-score* and *heterocentrism* outcomes are roughly 10% of the political liberalism coefficient, one of the most prognostic covariates determining prosocial attitudes toward LGBTQ+ people (Flores, 2014).

⁴⁶Study 3's coefficients, which are substantively larger, are from a telephone survey, where respondents are typically more attentive.

C.6 Temporal Placebo Tests

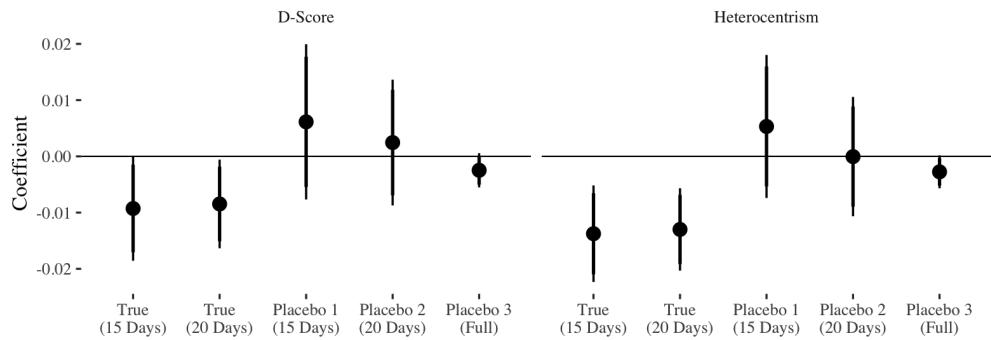

Figure C32: Comparing True *post-Pulse* Coefficient to Placebo Coefficients To Rule Out Pre-Treatment Temporal Trends That Motivate Pro-Gay Attitudes. The x-axis is the type of estimate. True (15 days) is the true *post-Pulse* coefficient using a 15-day bandwidth. True (20 days) is the same with a 20-day bandwidth. Placebo 1 estimates the influence of taking the IAT in the 15 days prior to the Pulse massacre relative to the 16-30 days prior to the Pulse massacre. Placebo 2 estimates the influence of taking the IAT in the 20 days prior to the Pulse massacre relative to the 21-40 days prior to the Pulse massacre. Placebo 3 estimates the influence of taking the IAT after the median pre-treatment day (2016-03-07 to 2016-06-12) relative to the days before the median pre-treatment day (2016-01-01 to 2016-03-06). The y-axis is the coefficient. The left/right panel characterizes the influence of the true and placebo coefficients on the *D-score* and *heterocentrism*. 95% CIs displayed from HC2 robust SEs.

C.7 Prior and Post Year Temporal Placebo

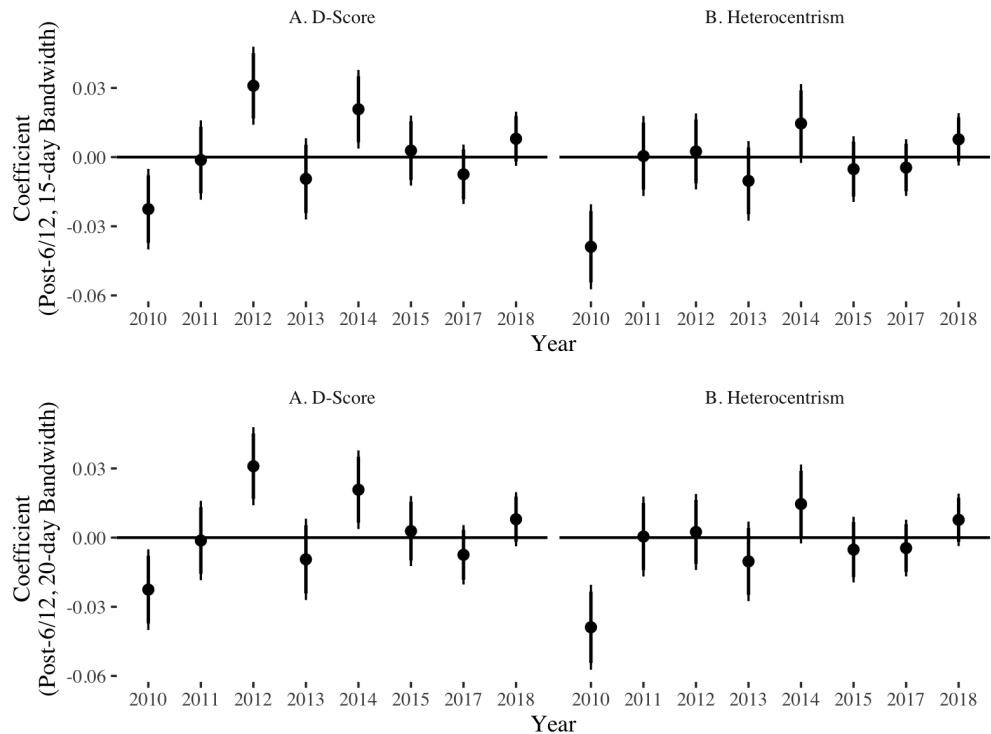

Figure C33: Temporal Placebo Tests Using IAT Data From Non-2016 Years. The x-axis is the IAT dataset at use (by year). The y-axis is the coefficient characterizing the influence of taking the IAT after June 12 (the calendar day of the Pulse nightclub shooting occurred). Panels A and B refer to estimates assessing the influence of the post-June 12th placebo on the *D-Score* and *Heterocentrism* outcomes. The top/bottom two panels are estimates using a 15/20 day bandwidth. 95% CIs displayed derived from HC2 robust standard errors.

C.8 Falsification Tests on Treatment-Irrelevant Group Attitudes

Table C48: Falsification Test on Treatment-Irrelevant Group Attitudes

Post-Pulse Coef.	SE	p	N	Outcome	Dataset	Bandwidth
-0.000	0.005	0.949	11310.000	D-Score	Black/White IAT	15 days

0.005	0.012	0.638	1745.000	D-Score	Arab/Non-Arab IAT	20 days
0.005	0.008	0.532	1663.000	Non-Arab Bias	Arab/Non-Arab IAT	20 days
0.005	0.009	0.543	1717.000	Ethnocentrism	Arab/Non-Arab IAT	20 days
-0.009	0.008	0.249	4213.000	D-Score	Dark Skin/Light Skin IAT	20 days
-0.003	0.006	0.604	6624.000	D-Score	Man/Woman (Career) IAT	20 days
0.007	0.008	0.416	3371.000	D-Score	Man/Woman (Science) IAT	20 days

This table characterizes falsification tests assessing the influence of taking an IAT *post-Pulse* on groups that are potentially unrelated to LGBTQ+. Not all datasets include the respective *D-score*, *bias*, and dominant group-centrism outcomes (hence their missingness in some IAT datasets). HC2 robust SEs displayed.

C.9 Evaluating Mechanisms

Table C49: Mechanism Tests Using IAT Data

	D-Score (1)	D-Score (2)	Heterocentrism (3)	Heterocentrism (4)	D-Score (5)	D-Score (6)	Heterocentrism (7)	Heterocentrism (8)	D-Score (9)	D-Score (10)	Heterocentrism (11)	Heterocentrism (12)
Post-Pulse x Non-White	0.01 (0.01)	0.01 (0.01)	0.02 (0.01)	0.00 (0.01)								
Post-Pulse x Woman					0.01 (0.01)	0.00 (0.01)	0.01 (0.01)	0.01 (0.01)				
Post-Pulse x Liberal									0.00 (0.01)	-0.01 (0.01)	-0.00 (0.01)	-0.01 (0.01)
R ²	0.01	0.00	0.01	0.00	0.00	0.00	0.00	0.00	0.09	0.09	0.14	0.13
N	3638	4907	3645	4920	3638	4907	3645	4920	3638	4907	3645	4920
Bandwidth (in Days)	15	20	15	20	15	20	15	20	15	20	15	20

Note: *** $p < 0.001$, ** $p < 0.01$, * $p < 0.05$. All covariates re-scaled between 0-1. Models do not include control covariates with the exception of the mechanism covariate that *post-Pulse* is being interacted with. HC2 robust standard errors in parentheses.

C.10 Balance Tests After Removing Days After Pulse Event

Table C50: Covariate Balance Tests After Cutting Days Immediately After Pulse Massacre

Days Cut	# Imbalanced Covariates	Imbalanced Covariates
1	0/12	
2	1/12	Florida
3	2/12	White, Florida
4	3/12	Liberal, White, Florida
5	2/12	Liberal, White
6	1/12	White

D Study 3: Matthew Shepard

D.1 Media Data Details

We collect data on the number of gay-related newspaper articles in the New York Times and Washington Post. Data on the number of gay-related NYT newspaper articles per month are from the NYT article API. We use the `rtimes` package to query data from the NYT article API. Gay-related NYT newspaper articles include the terms “homosexual” or “gay” in their text (Figure 6, Panel A). Shepard-related articles are gay-related NYT newspaper articles with the terms “wyoming,” “shepard,” “student,” “laramie,” “beat,” “beaten,” “bias,” and “hate (Figure 6, Panel C).”

Data on the number of gay-related Washington Post articles per month are acquired from the ProQuest Washington Post historical newspaper database (Figure 6, Panel B). Gay-related articles are those that include the terms “homosexual,” “gay,” or “homosexuality” in their text.

D.2 Homosexuality = Morally Wrong Outcome

D.2.1 Study Details

The two studies we use to assess if the belief homosexuality is immoral decreased after Shepard’s murder are the CNN/USA Today Jun 22-23 1998 poll and CNN/TIME Oct 14-15, 1998 poll. Both are nationally representative adult telephone surveys ($N = 1016$, $N = 1036$) and are population weighted to census demographic benchmarks. The CNN/USA Today poll was implemented by The Gallup Organization, and the CNN/TIME poll was implemented by Yankelovic Partners, Inc.

These two polls have largely similar sampling strategies (Voss et al., 1995). They are random digit dialing telephone polls. Their lists come from the same sample provider despite being implemented by different organizations (Survey Sampling Inc, SSI). Phone numbers are randomly selected based on a county’s contribution to the total number of telephone households (e.g. if a county contains 20% of the national population, a telephone number will be randomly selected from that county with a probability of 20%). The key difference between the two organizations is weighting. Gallup weighs their data to Census statistics along sex, race, Census region, age and education. Yankelovic weighs their data to Census statistics along Census region, sex, race, education, and marital status. Therefore, Gallup weighs on age unlike Yankelovic, but Yankelovic weighs on marital status unlike Gallup. We do not believe differences in weighting generate a significant problem for inference. First, across 20 baseline covariates, only 2/20 are statistically imbalanced between the two samples, suggesting the Yankelovic and Gallup sampling strategies produce relatively similar samples despite weighting differences (Figure 7, Panel A). Second, after adjusting for imbalance between the two surveys, the *post-Shepard* coefficient is stable, suggesting sampling/compositional differences may not serve as a strong source of bias (Figure 7, Panel B).

The outcome item of interest from the CNN/USA Today Jun 1998 poll is “do you personally believe homosexual behavior is morally wrong or is not morally wrong” with response choices of 1) Yes, morally wrong and 2) No, not morally wrong. The outcome is binary, equal to 1 if the respondent indicates “Yes, morally wrong.” The outcome item of interest from

the CNN/TIME Oct 1998 poll is “do you personally think that homosexual relationships between consenting adults is morally wrong, or not a moral issue?” with response choices of 1) Yes, morally wrong and 2) Not a moral issue. The outcome is binary, equal to 1 if the respondent indicates “Yes, morally wrong.” The weights, outcome, and baseline covariates are then stacked amongst each other across the two polls, with respondents from the CNN Oct. 1998 poll being defined as *post-Shepard* respondents (measured as a binary indicator equal to 1 if the respondent is from the October 1998 poll, 0 otherwise) and respondents from the CNN Jun. 1998 poll being defined as pre-Shepard respondents.

Although a benefit of these outcome items across the two surveys is they ask about the immorality of homosexuality very closely to the moment Matthew Shepard was murdered, they are worded slightly different from one another in that the post-Shepard survey references “homosexual relationships between consenting adults” while the pre-Shepard survey references “homosexual behavior.” Therefore, it is plausible the decrease in support for the belief homosexuality is morally wrong may be a function of the specification that the homosexual behavior referenced in the post-Shepard survey relates specifically to behavior among *consenting adults*. Consequently, we re-estimate our findings with a different pre-Shepard survey from 1994 with a similar item wording. Consistent with the main findings, we find that respondents interviewed after Shepard’s murder were less likely to believe homosexual relationships between consenting adults is morally wrong (see Figure 8). A shortcoming of the re-estimation is that our findings may be the result of secular time trends or intervening factors outside Shepard’s murder. These alternative explanations are unlikely. First, the temporal placebo test comparing attitudes regarding “homosexual behavior” between April 1997-June 1998 on Figure 7, Panel B is statistically null. These findings suggest attitudes regarding the immorality of homosexuality were not trending in a liberal direction between 1994 to 1998 prior to Shepard’s murder. Second, belief in the notion that “homosexual relationships between consenting adults” are “morally wrong” is *remarkably stable* between 1978-2004, with the exception of respondents interviewed in the few days after Matthew Shepard was murdered (Figure 8). These empirical findings suggest that item wording does not drive our main results and that Shepard’s murder shifted anti-gay attitudes and not other temporal intervening factors.

D.2.2 Temporal Placebo Details

To conduct a temporal placebo test ruling out secular trends that may drive our finding that respondents interviewed after Shepard’s murder were less likely to believe homosexuality is morally wrong, we use a third survey, the Gallup Apr 11-13 1997 poll. The Gallup Apr 1997 poll is a nationally representative telephone survey ($N = 1003$) and is population weighted to census demographic benchmarks. The Gallup Apr 1997 poll includes an item asking respondents if they “personally believe homosexual behavior is morally wrong or is not morally wrong” with responses 1) Yes, morally wrong and 2) No, not morally wrong. We then compare the average level of support for belief homosexual behavior is morally wrong between the Gallup Apr. 1997 poll and CNN Jun. 1998 poll.

Note: *** $p < 0.001$, ** $p < 0.01$, * $p < 0.05$, † $p < 0.1$. Sample is a stacked dataset of surveys with similar items on the covariates displayed on this table. Surveys included in this sample are the TIME 1978, CNN 1992, CNN 1994, CNN 1998, CNN 2001, and CNN 2004 polls. The reference category for the “year” analysis is based on the level of *moral wrong* in the CNN 1994 poll. HC2 robust standard errors in parentheses.

D.4 Alternative Outcomes

We found two other items that could serve as potential candidates for assessing the influence of Shepard’s murder on attitudes toward LGBTQ+ group members, however, we do not use them for various reasons. One item measured support for *legal recognition* of “marriages between homosexuals.” But, there is a 3-year interval between the two surveys including this outcome item (Gallup Mar. 1996, $N = 1008$, Gallup Feb. 1999, $N = 1054$), and there are no surveys with comparable items concerning legal recognition of marriages between homosexuals prior to the baseline time period to conduct temporal placebo tests. Nevertheless, respondents surveyed *post-Shepard* are more likely to support legally recognizing same-sex marriage, consistent with **H1** (see Section D.4.1 for details). Another item measures support for homosexuals serving in the armed forces using two surveys 7 months apart (*hire military*, Newsweek Jul. 1998, $N = 602$; Gallup Feb. 1999, $N = 1054$). Consistent with **H1**, we find respondents interviewed *post-Shepard* were more likely to support homosexuals serving in the military (Figure D35, Panel B). However, these effects may be a function of a secular attitudinal trend in support of incorporating homosexuals in the military, perhaps buttressed by Bill Clinton’s efforts to implement Don’t Ask Don’t Tell in the 1990s. We demonstrate this is the case by showing that support for hiring gay people in the military is on an increasing trend from 1977-1996 (Figure D35, Panel C). Conversely, the *moral wrong* outcome is remarkably stable prior to Shepard’s murder, making it an ideal candidate for assessing attitudinal shifts *post-Shepard* and their temporal sustainability (Figure 8).

D.4.1 Alternative Outcome: Legal Recognition

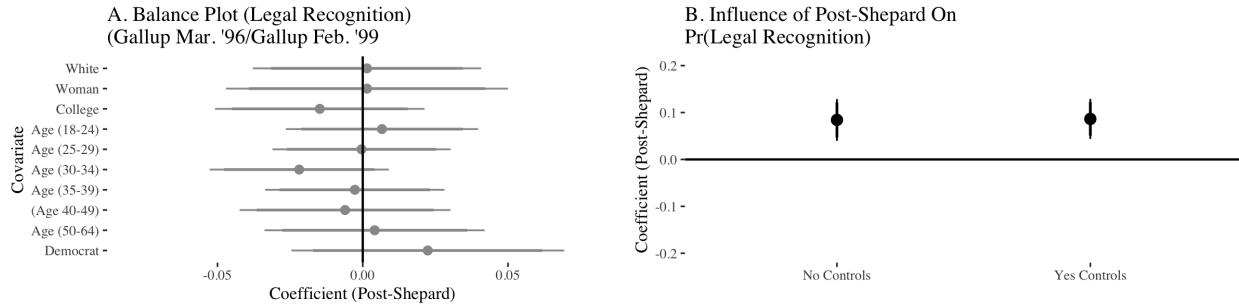

Figure D34: Influence of Shepard's Murder on Support for Legal Recognition of Same-Sex Marriages. All estimates include population weights. All covariates are scaled between 0-1. 95% CIs displayed derived from HC2 robust standard errors.

Data are from two polls stacked together. The first poll is the Gallup March 1996 Politics Polls ($N = 1008$). It was fielded from March 15-17, 1996 and is a telephone survey. The second poll is the Gallup February 1999 Service Poll ($N = 1054$). It was fielded from February 8-9, 1999. The main outcome of interest for this analysis is *legal recognition*. Legal recognition is from a common item in these two polls that asks respondents if they “think marriages between homosexuals should or should not be recognized by the law as valid, with the same rights as traditional marriages.” Respondents can choose to reply “should be valid” or “should not be recognized.” The outcome is measured equal to 1 if the respondent replies with “should be valid,” and 0 otherwise. Figure D34, Panel A displays covariate composition balance between the pre- (Gallup 1996) and *post-Shepard* (Gallup 1999) surveys. Panel B displays the influence of being interviewed in the *post-Shepard* survey on respondents reporting that they believe marriages between homosexual should be recognized by the law as valid. Respondents interviewed *post-Shepard* report a 8 percentage point increase in support for the belief homosexuals should have their marriages legally recognized.

D.4.2 Alternative Outcome: Hire Military

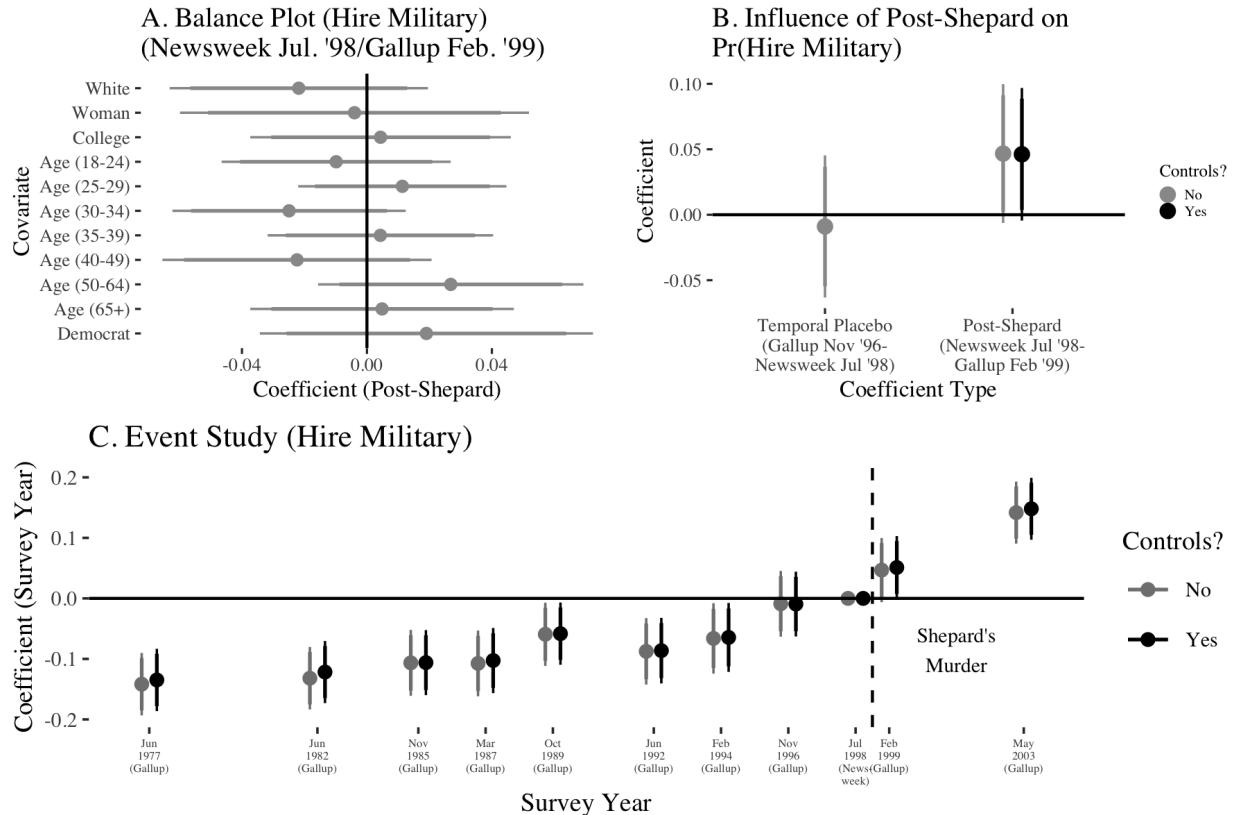

Figure D35: Influence of Shepard's Murder on Support for Hiring Gay People To Serve In The Military. Panel A displays covariate balance between the Newsweek Jul '98 and Gallup Feb '99 polls used to assess the influence of being interviewed *post-Shepard* on attitudes toward hiring gay people to serve in the military. Panel B displays a temporal placebo test assessing if mass attitudes on hiring gay people in the military shift between Nov '96 and Jul '98 in addition to coefficients with and without covariate adjustment that assess the influence of being interviewed *post-Shepard* on support for hiring gay people in the military. Panel C displays an event study assessing trends in support for hiring gay people in the military relative to a survey in Jul 1998 (hence no CIs for that survey estimate). All estimates include population weights. All covariates are scaled between 0-1. 95% CIs displayed derived from HC2 robust standard errors.

The two studies we use to assess if the belief homosexuals should be hired for the military increases after Shepard's murder are a Newsweek Jul. 30-31 1998 poll and a Gallup Feb. 8-9 1999 poll. Both are nationally representative adult telephone surveys ($N = 602$, $N = 1054$) and are population weighted to census demographic benchmarks.

The outcome item of interest from the Newsweek poll is "Tell me if you think gays and lesbians should be hired as members of the armed forces" with response choices of 1) Should and 2) Should not. The outcome is binary, equal to 1 if the respondent indicates "Should." The outcome item of interest from the Gallup poll is "Do you think homosexuals should or

should not be hired for the armed forces” with response choices of 1) Should and 2) Should not. The weights, outcome, and baseline covariates are then stacked amongst each other across the two polls, with respondents from the Gallup Feb. 1999 poll being defined as *post-Shepard* respondents (measured as a binary indicator equal to 1 if the respondent is from the October 1998 poll, 0 otherwise) and respondents from the Newsweek Jul. 1998 poll being defined as pre-Shepard respondents.

To conduct a temporal placebo test ruling out secular trends that may drive our finding that respondents interviewed after Shepard’s murder were more likely to support hiring homosexuals in the military, we use a third survey, the Gallup Nov 21-24 1996 poll. The Gallup Nov 1996 poll is a nationally representative telephone survey ($N = 1003$) and is population weighted to census demographic benchmarks. The Gallup Nov 1996 poll includes an item asking respondents if they think “homosexuals should or should be hired for the armed forces” with responses 1) Should and 2) Should not. We then compare the average level of support for whether homosexuals should be hired for the armed forces in the Gallup 1996 poll with the Newsweek 1998 poll.

Figure D35, Panel A, demonstrates that respondents interviewed before and after Shepard’s murder are similar on demographic, socio-economic, and political covariates. Figure D35, Panel B demonstrates that respondents interviewed *post-Shepard* are more likely to support gay people serving in the armed forces by 5 percentage points ($p < 0.10$), equivalent to 9% of the outcome standard deviation. However, Figure D35, Panel C demonstrates that support for hiring gay people in the military is on an upward trend between 1977-1996, suggesting these results may be a function of a progressive secular trend in support of incorporating gay people in the military, perhaps the result of Bill Clinton’s push for Don’t Ask Don’t Tell policies.

D.5 Temporal Persistence Data Details

TIME 1978 poll ($N = 1044$): Nationally representative telephone poll sponsored by TIME magazine. Fielded March 14-30, 1978. Item we use asks respondents if “do you personally think that homosexual relationships between consenting adults is morally wrong or not a moral issue. How about? 1) Morally wrong, 2) Not a moral issue” Outcome is coded 1 if respondent indicates “morally wrong.”

CNN 1992 poll ($N = 1250$): Nationally representative telephone poll sponsored by TIME magazine and CNN. Fielded May 13-14, 1992. Item we use asks respondents if “do you personally think that homosexual relationships between consenting adults is morally wrong or not a moral issue. How about? 1) Morally wrong, 2) Not a moral issue” Outcome is coded 1 if respondent indicates “morally wrong.”

CNN 1994 poll ($N = 800$): Nationally representative telephone poll sponsored by TIME magazine and CNN. Fielded June 15-16, 1994. Item we use asks respondents if “do you personally think that homosexual relationships between consenting adults is morally wrong or not a moral issue. How about? 1) Morally wrong, 2) Not a moral issue.” Outcome is coded 1 if respondent indicates “morally wrong.”

CNN 1998 poll ($N = 1036$): Nationally representative telephone poll sponsored by TIME magazine and CNN. Fielded October 14-15, 1998. Item we use asks respondents if “do you personally think that homosexual relationships between consenting adults is morally wrong or not a moral issue. How about? 1) Morally wrong, 2) Not a moral issue.” Outcome is coded 1 if respondent indicates “morally wrong.”

CNN 2001 poll ($N = 1000$): Nationally representative telephone poll sponsored by TIME magazine and CNN. Fielded January 10-11, 2001. Item we use asks respondents if “do you personally think that homosexual relationships between consenting adults is morally wrong or not a moral issue. How about? 1) Morally wrong, 2) Not a moral issue.” Outcome is coded 1 if respondent indicates “morally wrong.”

CNN 2004 poll ($N = 1000$): Nationally representative telephone poll sponsored by TIME magazine and CNN. Fielded February 5-6, 2004. Item we use asks respondents if “do you personally think that homosexual relationships between consenting adults is morally wrong or not a moral issue. How about? 1) Morally wrong, 2) Not a moral issue.” Outcome is coded 1 if respondent indicates “morally wrong.”

D.6 Falsification Test Outcome Details

Outcome: Ban Abortion. **Surveys:** CNN Jan. '98, CNN Newsweek Oct. '98. **Pre-Shepard Outcome:** "Do you think abortions should be 1) legal under any circumstance, 2) legal under certain circumstances, or 3) illegal in all circumstances." Coded 1 if respondent indicates "legal under any circumstance" and 0 otherwise. **Post-Shepard Outcome:** Same as pre-Shepard

Outcome: Affirmative Action 1. **Surveys:** CBS Dec. '97, CBS Jul. '00. **Pre-Shepard Outcome:** "In order to make up for past discrimination, do you favor or oppose programs which make special efforts to help minorities get ahead?" 1) Favor, 2) Oppose. Coded 1 if respondent indicates favor, 0 otherwise. **Post-Shepard Outcome:** Same as pre-Shepard

Outcome: Affirmative Action 2. **Surveys:** ANES 96-'98. **Pre-Shepard Outcome:** "Some people say that because of past discrimination, blacks should be given preference in hiring and promotion. Others say that such preference in hiring and promotion of blacks is wrong because it gives blacks advantages they haven't earned. What about your opinion – are you FOR or AGAINST preferential hiring and promotion of blacks?" 1) For preferential hiring and promotion of blacks, 2) Against preferential hiring and promotion of blacks. Coded 1 if respondent indicates for preferential hiring, 0 otherwise. **Post-Shepard Outcome:** Same as pre-Shepard

Outcome: Death Penalty. **Surveys:** Kaiser Jul. '98, Gallup Feb. '99 **Pre-Shepard Outcome:** "Do you favor or oppose the death penalty for persons convicted of murder?" 1) Favor, 2) Oppose. Coded 1 if favor, 0 otherwise. **Post-Shepard Outcome:** "Are you in favor of the death penalty for a person convicted of murder?" 1) Yes, in favor, 2) No, not in favor. Coded 1 if favor, 0 otherwise.

Outcome: Black People are Unintelligent. **Surveys:** GSS '98-'00. **Pre-Shepard Outcome:** "Do people in these groups tend to be unintelligent or tend to be intelligent? Where you rate Blacks in general on this scale?" 1-7 scale from 1 = unintelligent to 7 = intelligent, reverse coded and rescaled between 0-1. **Post-Shepard Outcome:** Same as pre-Shepard

Outcome: Spending Too Little on Helping Black People **Surveys:** GSS '98-'00. **Pre-Shepard Outcome:** "We are faced with many problems in this country, none of which can be solved easily or inexpensively. I'm going to name some of these problems, and for each one I'd like you to tell me whether you think we're spending too much money on it, too little money, or about the right amount: improving the conditions of Blacks" Coded 1 if too little, 0 otherwise. **Post-Shepard Outcome:** Same as pre-Shepard

Outcome: Black-White Inequality is Because of Discrimination. **Surveys:** GSS '98-'00. **Pre-Shepard Outcome:** "On the average (Negroes/Blacks/African-Americans) have worse jobs, income, and housing than white people. Do you think these differences are: mainly due to discrimination" 1) Yes, 2) No. Coded 1 if yes, 0 otherwise. **Post-Shepard Outcome:** Same as pre-Shepard

Outcome: Black-White Inequality is Because of In-Born Ability. **Surveys:** GSS '98-'00. **Pre-Shepard Outcome:** "On the average (Negroes/Blacks/African-Americans) have worse jobs, income, and housing than white people. Do you think these differences are: Because most (Negroes/Blacks/African-Americans) have less in-born ability to learn?" 1) Yes, 2) No. Coded 1 if yes, 0 otherwise. **Post-Shepard Outcome:** Same as pre-Shepard

Outcome: Black-White Inequality is Because of No Chance for Education. **Surveys:** GSS '98-'00. **Pre-Shepard Outcome:** "On the average (Negroes/Blacks/African-Americans) have worse jobs, income, and housing than white people. Do you think these differences are: Because most (Negroes/Blacks/African-Americans) don't have the chance for education that it takes to rise out of poverty?" 1) Yes, 2) No. Coded 1 if yes, 0 otherwise. **Post-Shepard Outcome:** Same as pre-Shepard

Outcome: Black-White Inequality is Because of No Motivation. **Surveys:** GSS '98-'00. **Pre-Shepard Outcome:** "On the average (Negroes/Blacks/African-Americans) have worse jobs, income, and housing

than white people. Do you think these differences are: Because most (Negroes/Blacks/African-Americans) just don't have the motivation or will power to pull themselves up out of poverty?" 1) Yes, 2) No. Coded 1 if yes, 0 otherwise. **Post-Shepard Outcome:** Same as pre-Shepard

Outcome: Oppose Living with Black People. **Surveys:** GSS '98-'00. **Pre-Shepard Outcome:** "Now I'm going to ask you about different types of contact with various groups of people. In each situation would you please tell me whether you would be very much in favor of it happening, somewhat in favor, neither in favor nor opposed to it happening, somewhat opposed, or verymuch opposed to it happening? Living in a neighborhood where half of your neighbors were blacks?" 1-5 scale from 1 = Strongly Favor to 5 = Strongly Oppose. Coded 1 if oppose or strongly oppose, 0 otherwise. **Post-Shepard Outcome:** Same as pre-Shepard

Outcome: Black Feeling Thermometer. **Surveys:** ANES '96-'98. **Pre-Shepard Outcome:** "How would you rate Blacks?" 0-100 scale, rescaled between 0-1. **Post-Shepard Outcome:** Same as pre-Shepard

Outcome: Abortion Any Time. **Surveys:** GSS '98-'00. **Pre-Shepard Outcome:** 'Please tell me whether or not you think it should be possible for a pregnant woman to obtain a legal abortion if the woman wants it for any reason?' 1 if yes. **Post-Shepard Outcome:** Same as pre-Shepard

Outcome: Support Female Politicians. **Surveys:** GSS '98-'00. **Pre-Shepard Outcome:** "Tell me if you agree or disagree with this statement: Most men are better suited emotionally for politics than are most women" 1 if agree, 0 otherwise. **Post-Shepard Outcome:** Same as pre-Shepard

Outcome: Working Women Good. **Surveys:** GSS '98-'00. **Pre-Shepard Outcome:** "Now I'm going to read several more statements. As I read each one, please tell me whether you strongly agree, agree, disagree, or strongly disagree with it. For example, here is the statement: A working mother can establish just as warm and secure a relationship with her children as a mother who does not work." 1 if agree, 0 otherwise. **Post-Shepard Outcome:** Same as pre-Shepard

Outcome: Working Women Bad 1. **Surveys:** GSS '98-'00. **Pre-Shepard Outcome:** "Now I'm going to read several more statements. As I read each one, please tell me whether you strongly agree, agree, disagree, or strongly disagree with it. For example, here is the statement: A preschool child is likely to suffer if his or her mother works." 1 if agree, 0 otherwise. **Post-Shepard Outcome:** Same as pre-Shepard

Outcome: Working Women Bad 2. **Surveys:** GSS '98-'00. **Pre-Shepard Outcome:** "Now I'm going to read several more statements. As I read each one, please tell me whether you strongly agree, agree, disagree, or strongly disagree with it. For example, here is the statement: It is much better for everyone involved if the man is the achiever outside the home and the woman takes care of the home and family." 1 if agree, otherwise. **Post-Shepard Outcome:** Same as pre-Shepard

D.7 Assessing If Violence Against LGBTQ+ Community Segments Was Salient in 4 Months Between Surveys

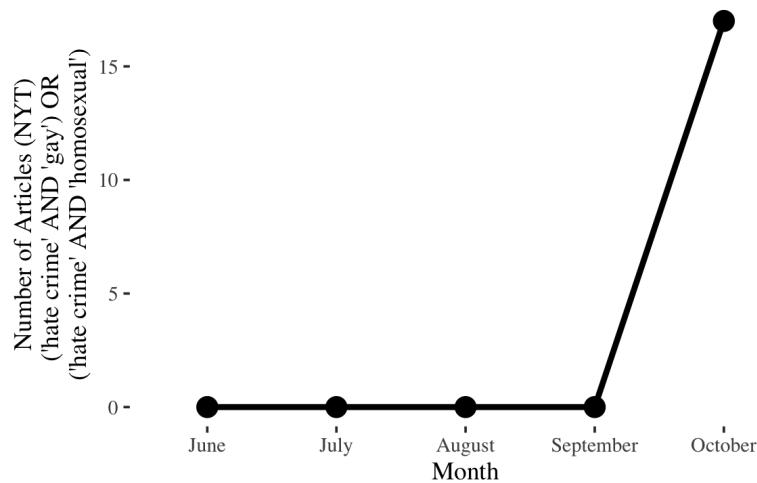

Figure D36: There Was No New York Times Coverage of Hate Crimes Related to Gay People In Between June-October 1998. The x-axis is the month of 1998, the y-axis is the count of articles identified in the New York Times Historic Database (ProQuest) that are related to the following search term: (“hate crime” AND “gay”) OR (“hate crime” AND “homosexual”)

E Comparing Salience of Shepard and Pulse Events To Other Instances of Anti-LGBTQ+ Violence

E.1 Salience: Search Rules

Here, we assess the salience of several relatively prominent anti-LGBTQ+ violent events relative to the Pulse massacre and Matthew Shepard's murder. The universe of events we assess is from this list: https://en.wikipedia.org/wiki/History_of_violence_against_LGBT_people_in_the_United_States. To assess salience, we assess the number of search hits related to each event from 1) Google Search, 2) Google News, 3) Google Scholar, 4) New York Times, and 5) Washington Post.

The search term we use to assess salience is: “[name of victim] AND LGBT OR LGBTQ OR gay OR lesbian OR bisexual OR queer OR transgender OR trans OR homophobic OR transphobic AND attack OR assault OR murder OR kill OR killed OR killing OR death”

E.2 Salience: Google Search Hits

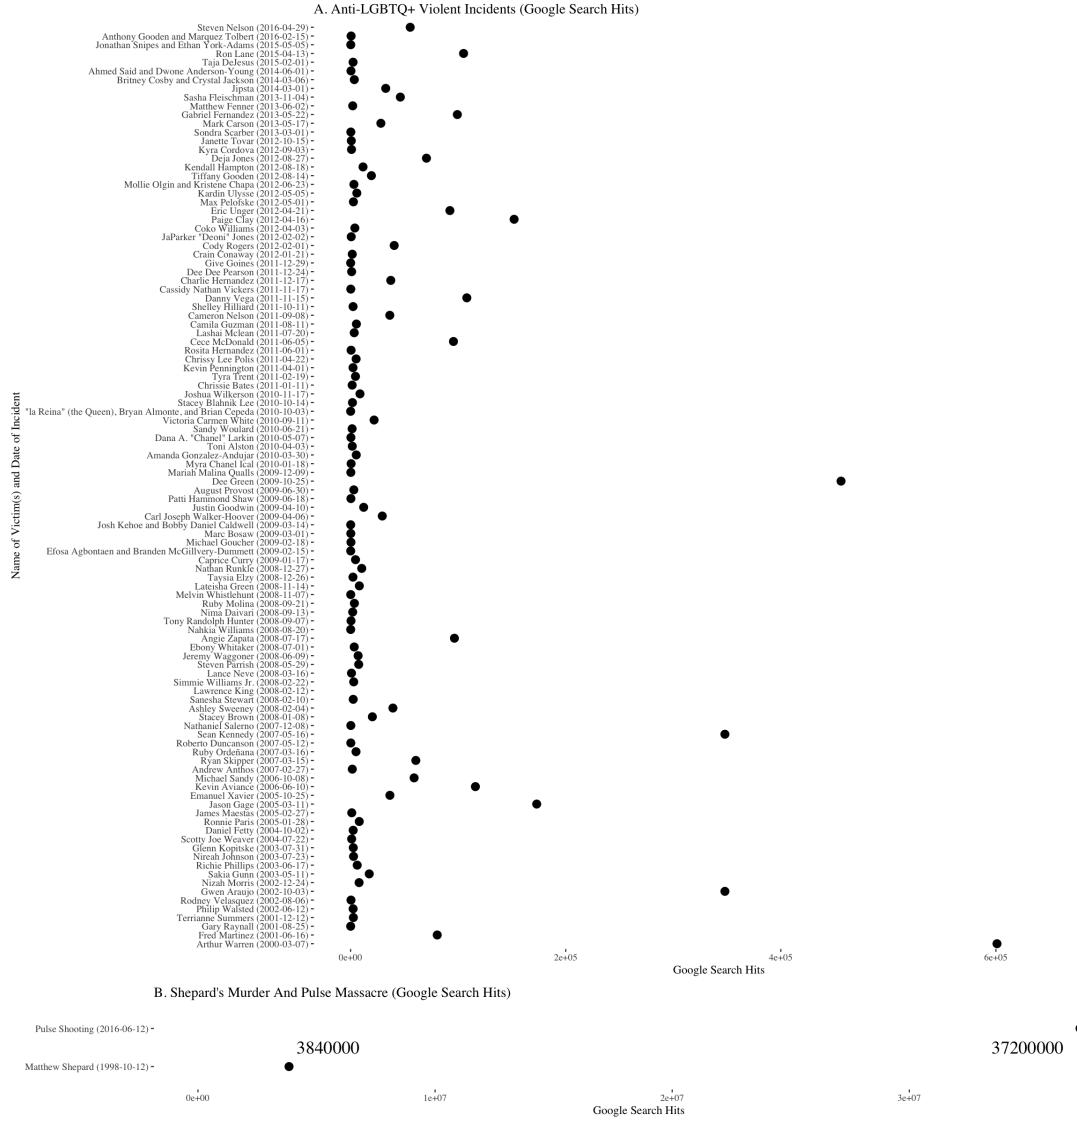

Figure E37: Salience of Pulse Massacre and Matthew Shepard's Murder Relative To Other Prominent Instances of Anti-LGBTQ+ Violence (Google Search Hits). Panel A characterizes the number of Google search hits (x-axis) related to relatively prominent anti-LGBTQ+ violence incidents between 2000-2016 (y-axis, based on this list: https://en.wikipedia.org/wiki/History_of_violence_against_LGBT_people_in_the_United_States) Panel B is the number of Google search hits (x-axis) related to the Pulse massacre and Matthew Shepard's murder (y-axis). Note the different y-axis for Panel B, demonstrating Shepard's murder and the Pulse massacre are much more salient than the other incidents. Annotations on Panel B denote number of hits.

E.3 Salience: Google News Hits

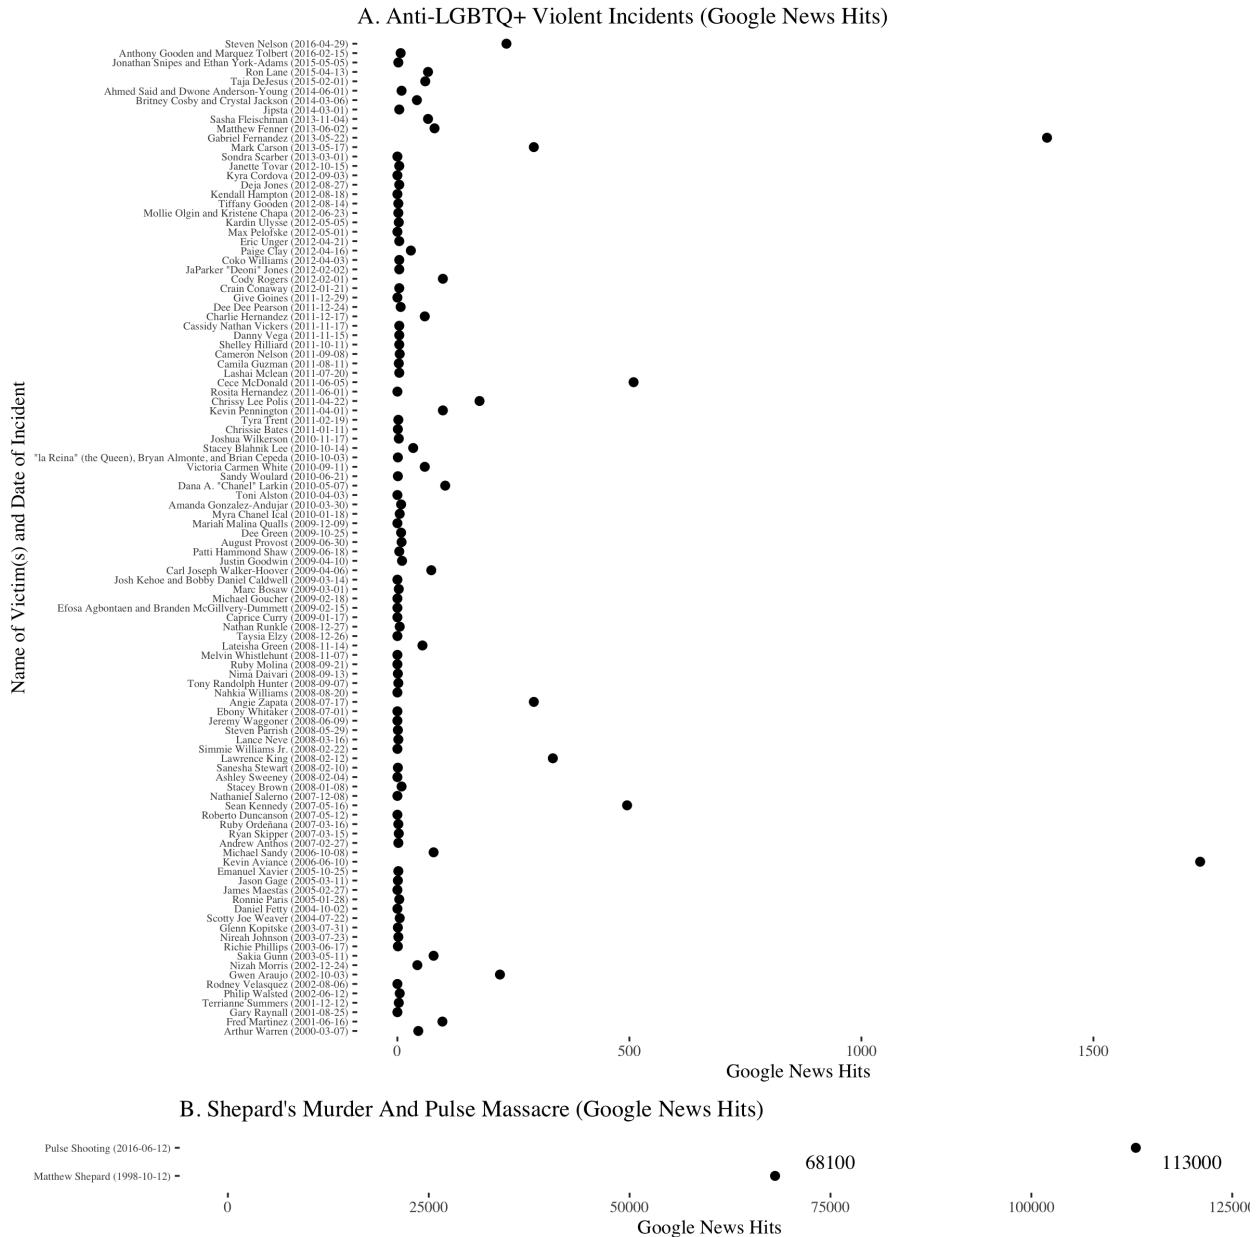

Figure E38: Salience of Pulse Massacre and Matthew Shepard's Murder Relative To Other Prominent Instances of Anti-LGBTQ+ Violence (Google News Hits). Panel A characterizes the number of Google news hits (x-axis) related to relatively prominent anti-LGBTQ+ violence incidents between 2000-2016 (y-axis, based on this list: https://en.wikipedia.org/wiki/History_of_violence_against_LGBT_people_in_the_United_States) Panel B is the number of Google news hits (x-axis) related to the Pulse massacre and Matthew Shepard's murder (y-axis). Note the different y-axis for Panel B, demonstrating Shepard's murder and the Pulse massacre are much more salient than the other incidents. Annotations on Panel B denote number of hits.

E.4 Salience: Google Scholar Hits

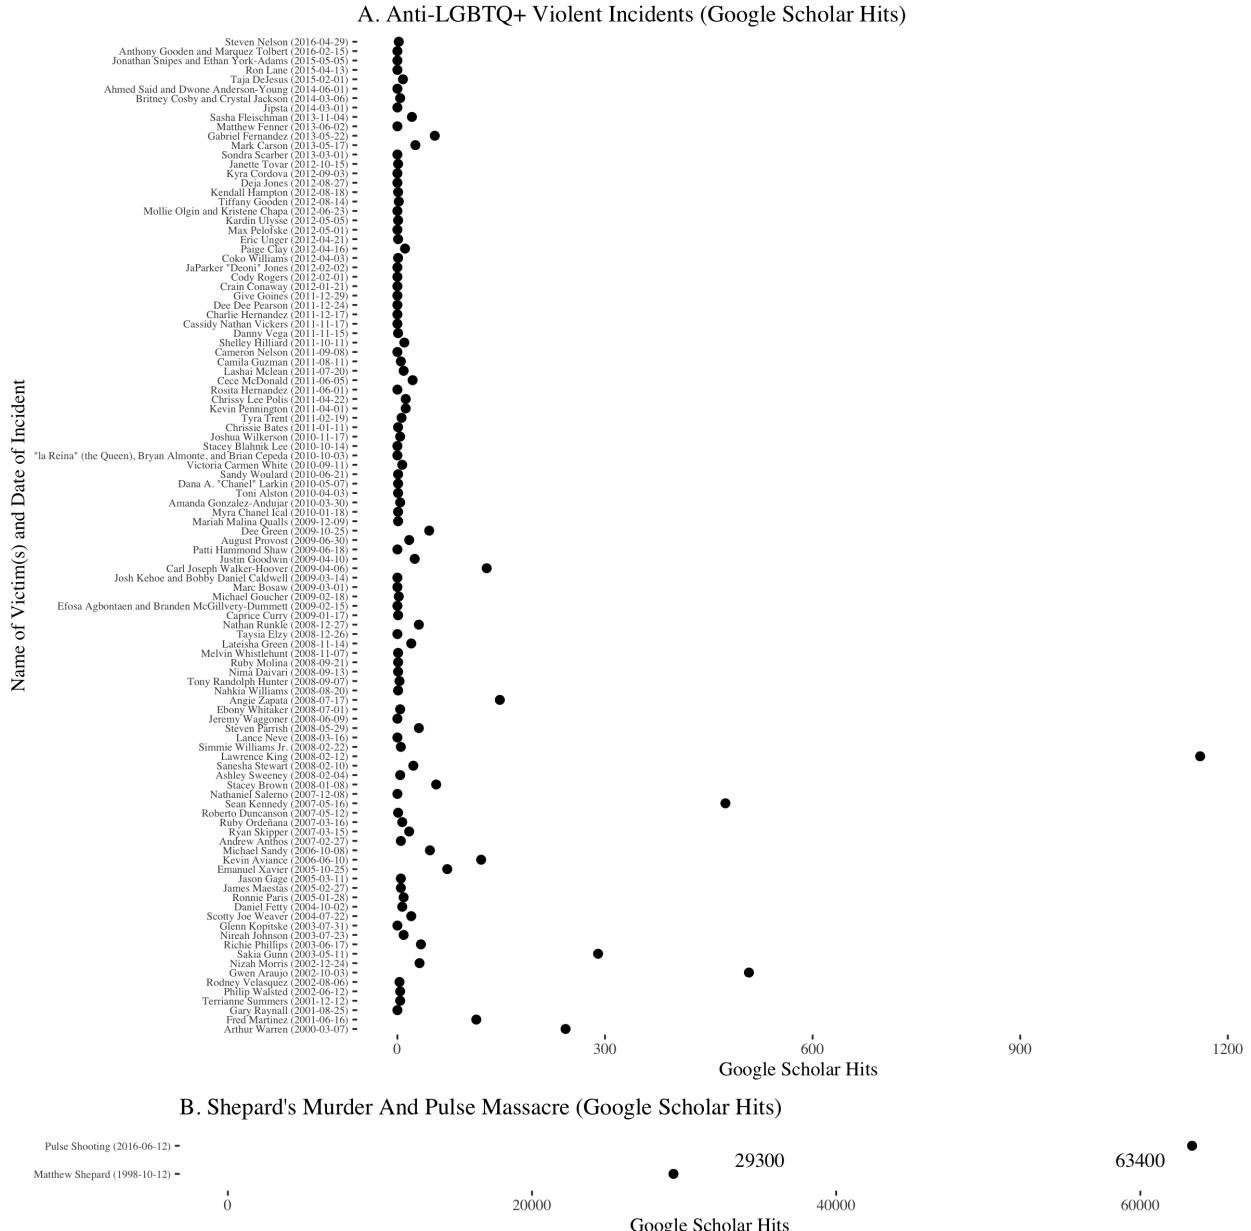

Figure E39: Salience of Pulse Massacre and Matthew Shepard's Murder Relative To Other Prominent Instances of Anti-LGBTQ+ Violence (Google Scholar Hits) Panel A characterizes the number of Google scholar hits (x-axis) related to relatively prominent anti-LGBTQ+ violence incidents between 2000-2016 (y-axis, based on this list: https://en.wikipedia.org/wiki/History_of_violence_against_LGBT_people_in_the_United_States) Panel B is the number of Google scholar hits (x-axis) related to the Pulse massacre and Matthew Shepard's murder (y-axis). Note the different y-axis for Panel B, demonstrating Shepard's murder and the Pulse massacre are much more salient than the other incidents. Annotations on Panel B denote number of hits.

E.5 Saliency: New York Times Hits

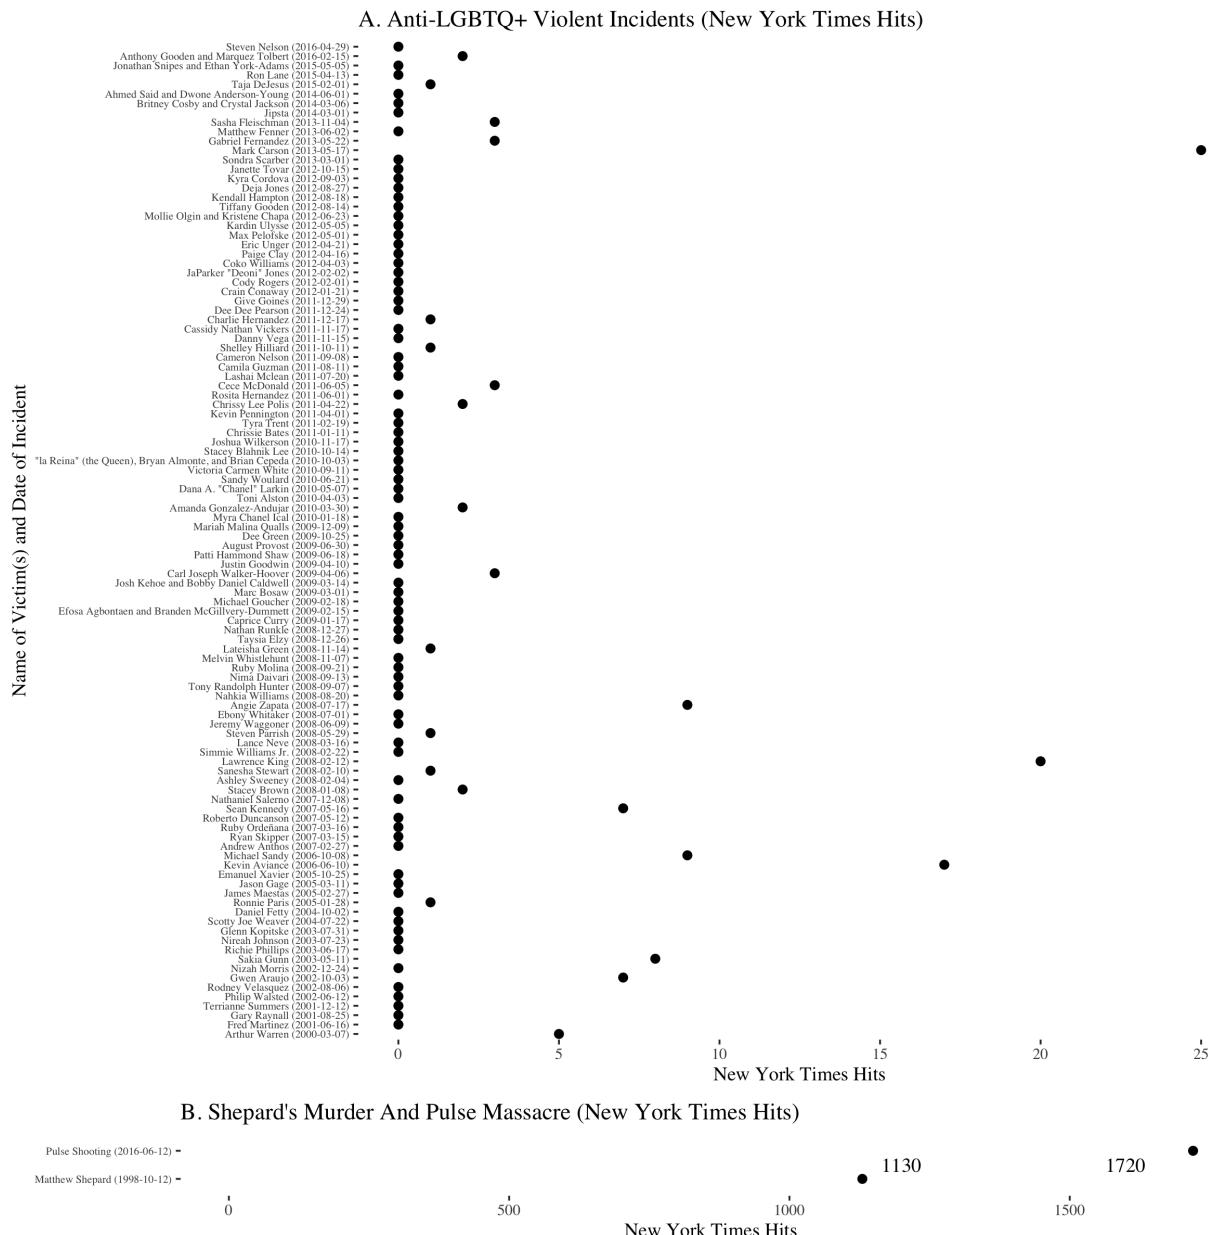

Figure E40: Saliency of Pulse Massacre and Matthew Shepard's Murder Relative To Other Prominent Instances of Anti-LGBTQ+ Violence (New York Times Hits) Panel A characterizes the number of New York Times hits (x-axis) related to relatively prominent anti-LGBTQ+ violence incidents between 2000-2016 (y-axis, based on this list: https://en.wikipedia.org/wiki/History_of_violence_against_LGBT_people_in_the_United_States) Panel B is the number of New York Times hits (x-axis) related to the Pulse massacre and Matthew Shepard's murder (y-axis). Note the different y-axis for Panel B, demonstrating Shepard's murder and the Pulse massacre are much more salient than the other incidents. Annotations on Panel B denote number of hits.

E.6 Saliency: Washington Post Hits

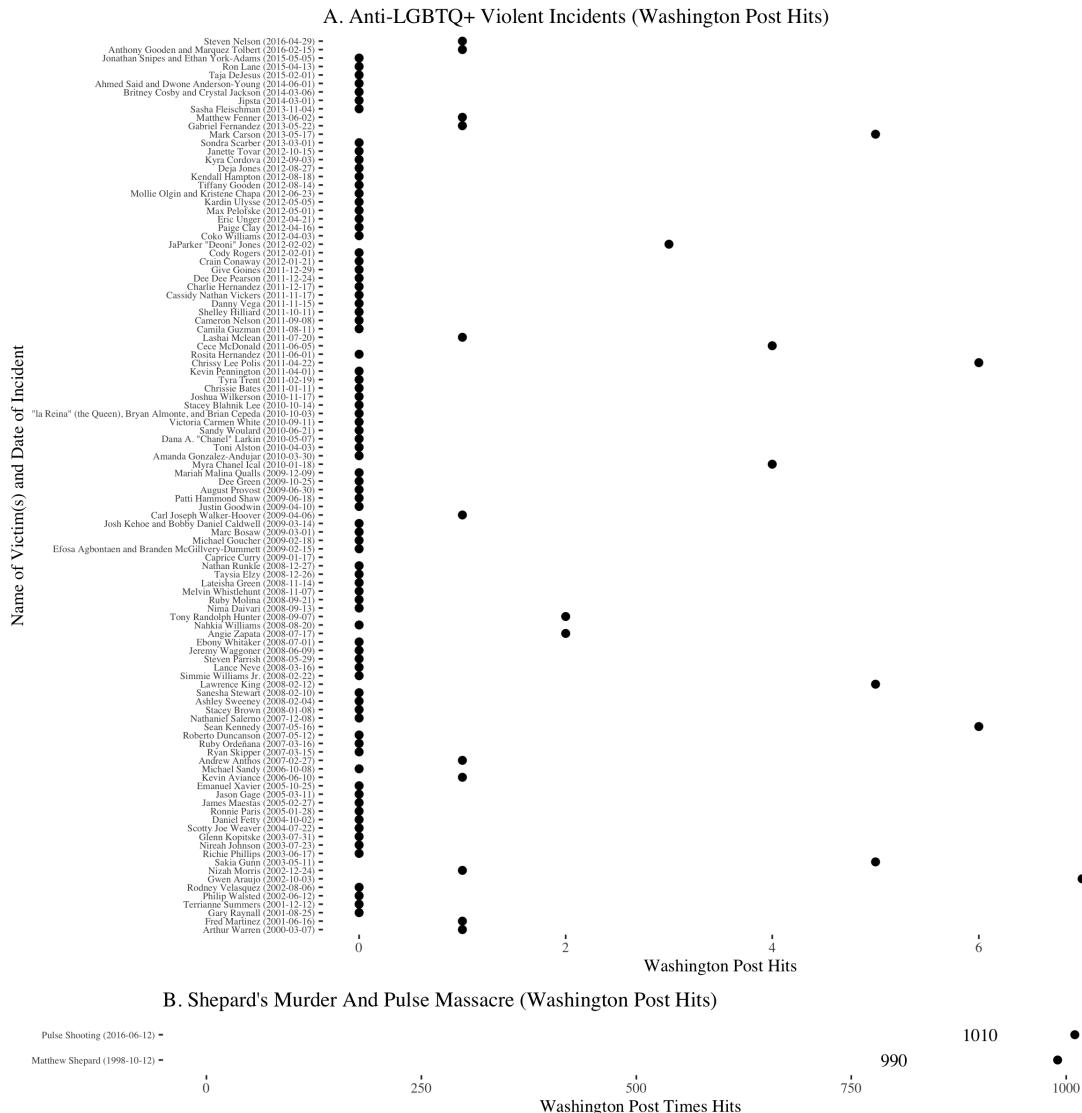

Figure E41: Saliency of Pulse Massacre and Matthew Shepard's Murder Relative To Other Prominent Instances of Anti-LGBTQ+ Violence (Washington Post Hits) Panel A characterizes the number of Washington Post hits (x-axis) related to relatively prominent anti-LGBTQ+ violence incidents between 2000-2016 (y-axis, based on this list: https://en.wikipedia.org/wiki/History_of_violence_against_LGBT_people_in_the_United_States) Panel B is the number of Washington Post hits (x-axis) related to the Pulse massacre and Matthew Shepard's murder (y-axis). Note the different y-axis for Panel B, demonstrating Shepard's murder and the Pulse massacre are much more salient than the other incidents. Annotations on Panel B denote number of hits.

E.7 Assessing Effect of Non-Shepard, Non-Pulse Anti-LGBTQ+ Violent Events

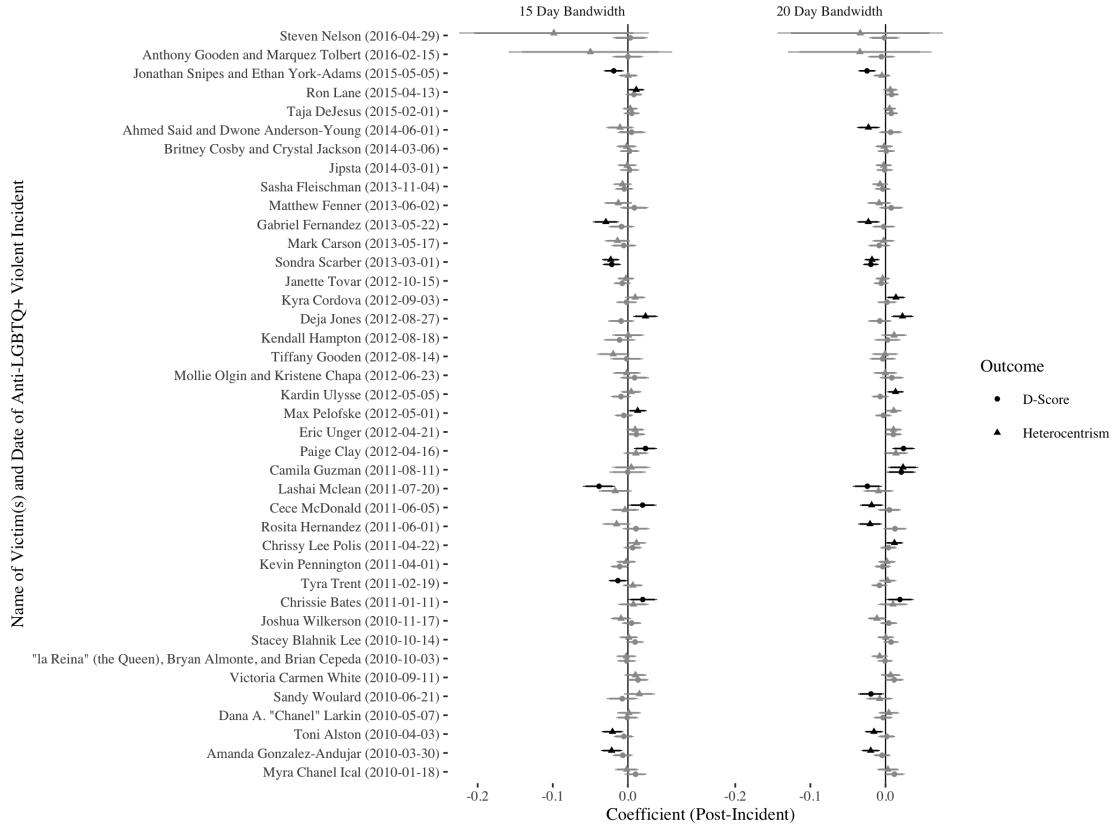

Figure E42: Effect of Non-Pulse, Non-Shepard, Anti-LGBTQ+ Violence Incidents on Anti-Gay Attitudes. The y-axis is each anti-LGBTQ+ violent incident between 2010-2016 before the Pulse massacre (name of victim(s) and date of incident, based on this list: https://en.wikipedia.org/wiki/History_of_violence_against_LGBT_people_in_the_United_States). The x-axis is the coefficient characterizing the effect of taking the Project Implicit Sexuality IAT Survey 15 and 20-days before and after the incident (*post-incident*, left and right panel respectively). Shape denotes the outcome (circle = *D-score*, triangle = *heterocentrism*). Anti-LGBTQ+ incidents between September 2011-December 2011 and January 2010-April 2010 are not included in the analyses due to the absence of Sexuality IAT data for U.S. adults who complete the survey. Black coefficients are statistically significant, grey otherwise. Consistent with the main results, all estimates are covariate-adjusted for age, gender, race, college-education, liberal ideology, religiosity, living in a metro area, and state-level indicators for California, Pennsylvania, New York, Florida, and Illinois. 95% CIs displayed from HC2 robust SEs.

F Replication: Club Q

F.1 Anti-Trans Attitudes Outcome Measurement Details

Anti-Trans D-Score: Measured by assessing the speed by which respondents associate negative/positive attributes (words) to images of trans/cis celebrities. Higher value suggest respondents associated negative attributes to trans people faster than they associated negative attributes to cis people. See Axt et al. (2021) for more details. This outcome is rescaled between 0-1 during the analysis.

Cis Bias: Scale from 1-7 from “I strongly prefer transgender people to cisgender people” to “I strongly prefer cisgender people to transgender people.” This outcome is rescaled between 0-1 during the analysis, with 1 indicating maximum preferences for cisgender people.

Ciscentrism: Measured with two scales. One scale asks respondents to rate how warm they feel toward transgender people on a scale between 1-10. The other scale asks respondents to rate how warm they feel toward cisgender people on a scale between 1-10. We subtract the scale on warmth toward transgender people from the scale on warmth toward cisgender people. Therefore, higher values suggest more relative warmth toward cisgender people than transgender people. We rescale this measure between 0-1, with 1 indicating maximum warmth toward cisgender people relative to transgender people.

F.2 Balance Tests

F.2.1 Project Implicit Sexuality IAT Data (2022)

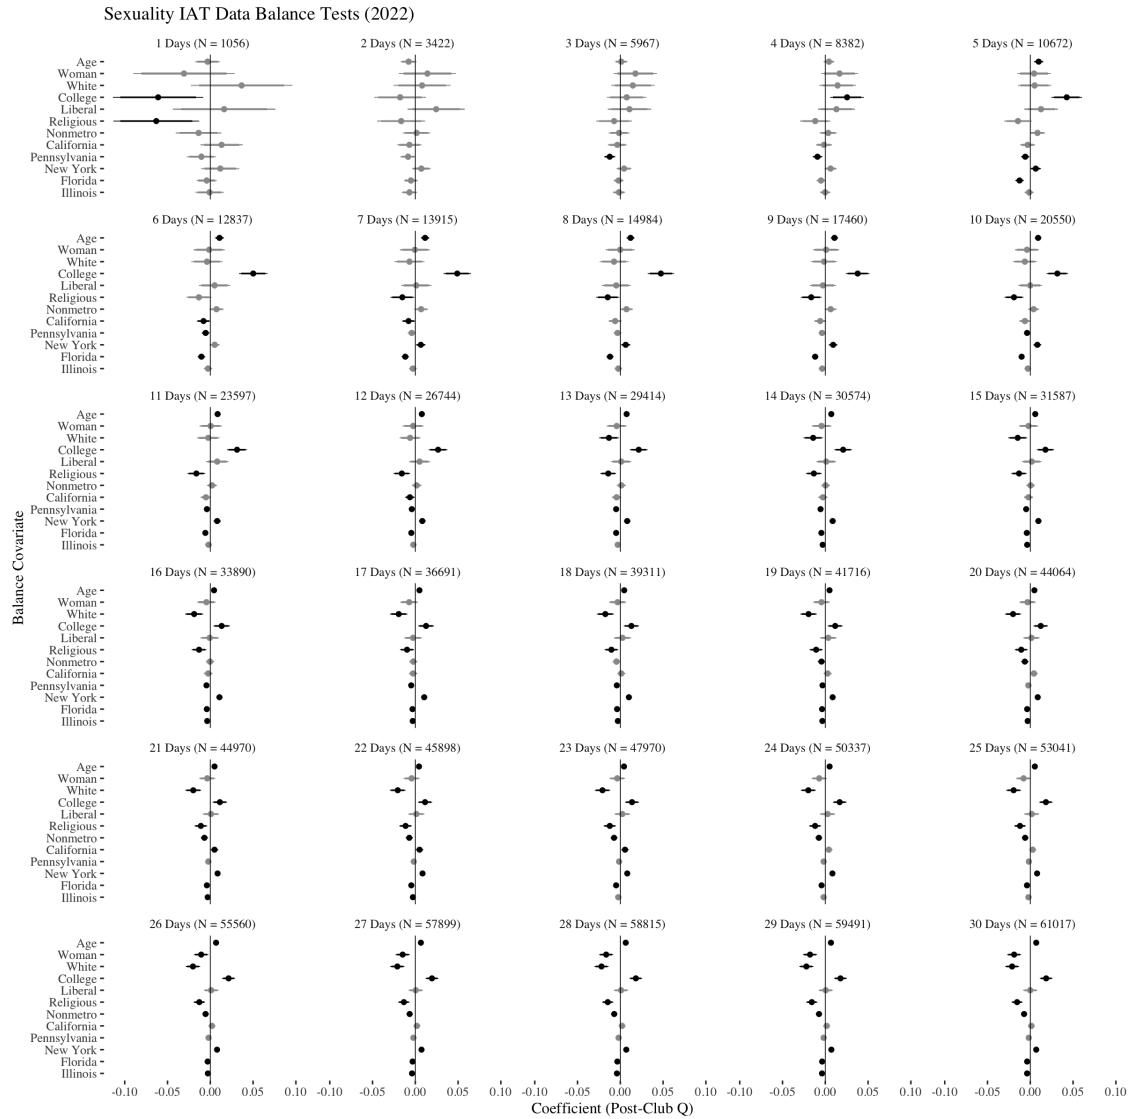

Figure F43: Covariate Balance Between Project Implicit Sexuality IAT Survey-Takers Before and After Club Q Massacre. Each coefficient is from a separate model regressing a balance covariate (y-axis) on a binary indicator for taking the Sexuality IAT after the Club Q massacre (*post-Club Q*). Each panel characterizes the sample bandwidth at use (1-30 days from the Club Q massacre) and sample size. Statistically significant coefficients are black, grey otherwise. 95% CIs displayed derived from HC2 robust standard errors.

F.2.2 Project Implicit Transgender IAT Data (2022)

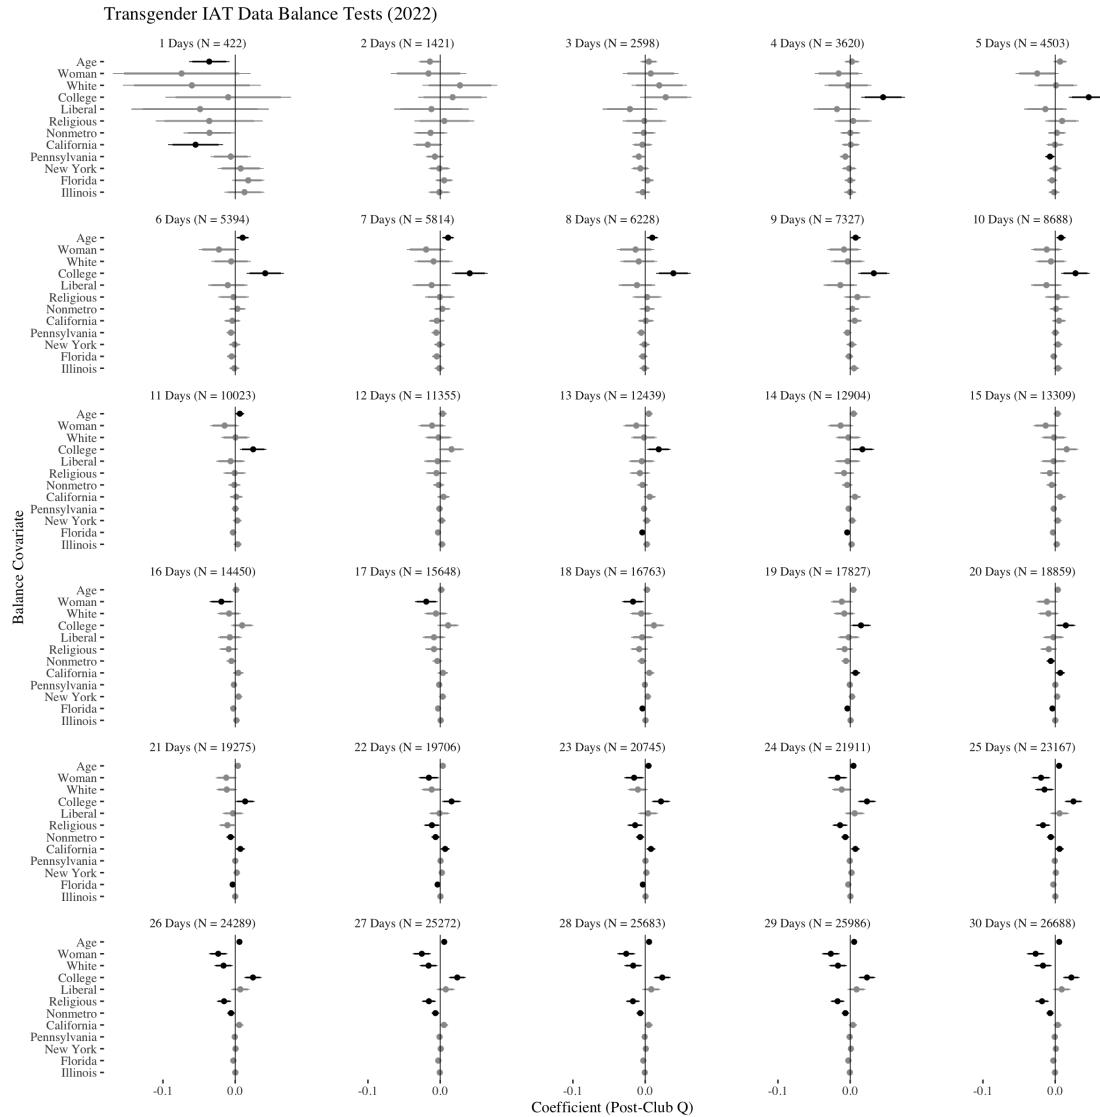

Figure F44: Covariate Balance Between Project Implicit Transgender IAT Survey-Takers Before and After Club Q Massacre. Each coefficient is from a separate model regressing a balance covariate (y-axis) on a binary indicator for taking the Transgender IAT after the Club Q massacre (*post-Club Q*). Each panel characterizes the sample bandwidth at use (1-30 days from the Club Q massacre) and sample size. Statistically significant coefficients are black, grey otherwise. 95% CIs displayed derived from HC2 robust standard errors.

F.3 Effect of Club Q on Anti-Gay, Anti-Trans Attitudes

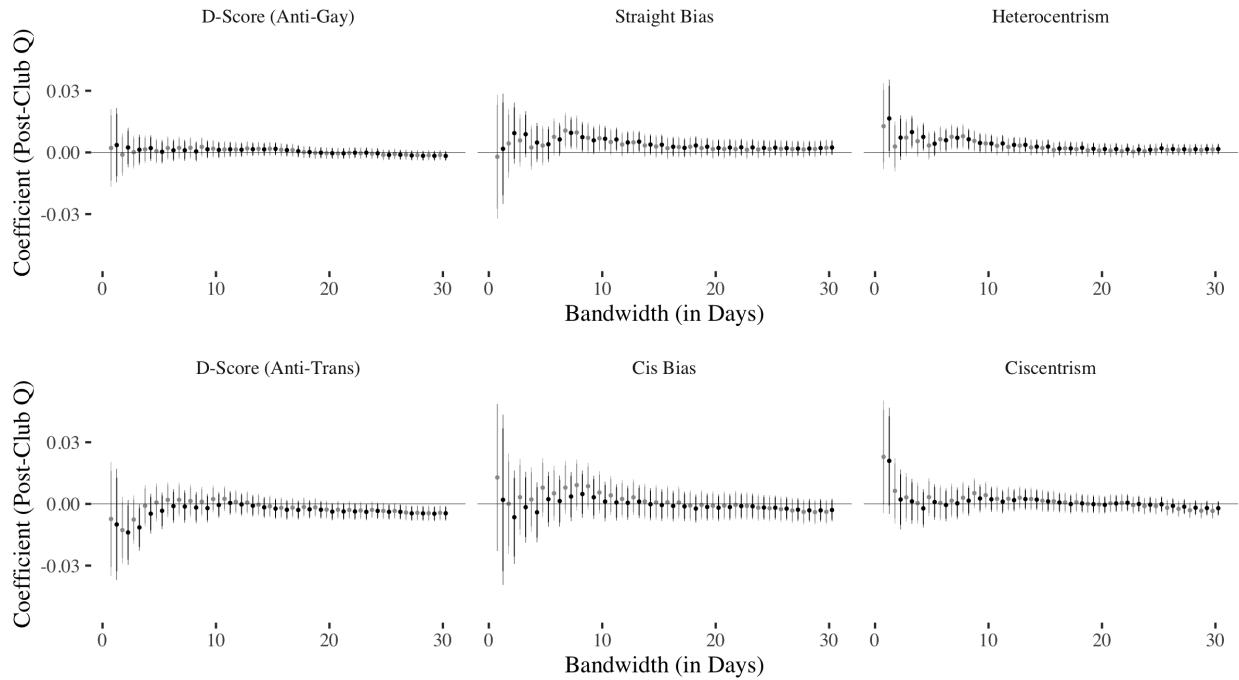

Figure F45: Effect of Club Q Massacre on Anti-Gay and Anti-Trans Attitudes. The x-axis characterizes the bandwidth sample at use (1-30 days). The y-axis is the *post-Club Q* coefficient. Each panel characterizes a different outcome. The top 3 panels characterize estimates from the 2022 Project Implicit Sexuality IAT data. The bottom 3 panels characterize estimates from the 2022 Project Implicit Transgender IAT data. Black coefficients are derived from models adjusting for control covariates, grey otherwise. 95% CIs displayed derived from HC2 robust standard errors.

F.4 Salience of Club Q Relative to Pulse and Shepard

F.4.1 Google Trends

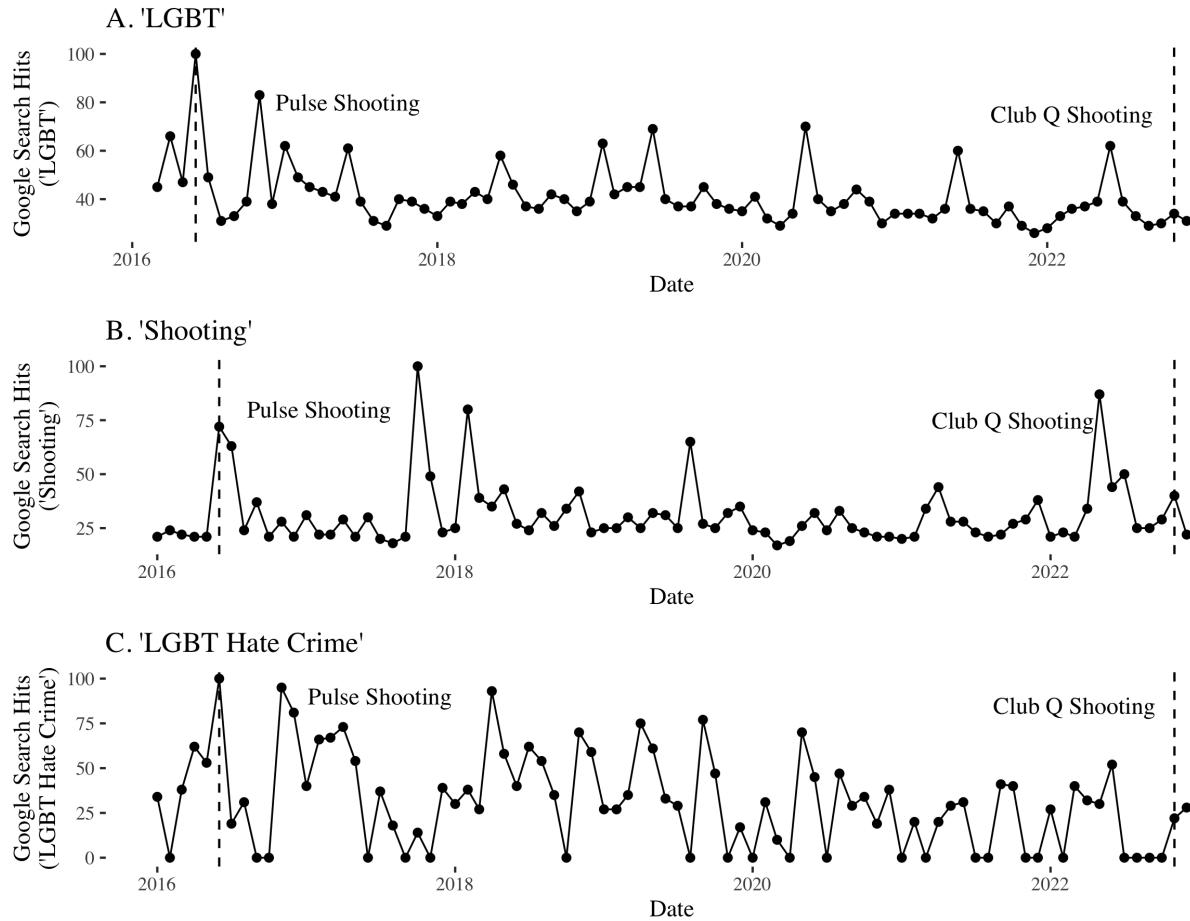

Figure F46: Google Search Intensity On Topics Related to LGBT, Hate Crimes, and Mass Shootings Over Time (2016-2022). The x-axis is month, the y-axis is the normalized search intensity for a particular search topic between 2016-2022. From left to right, dashed vertical lines denote the moment of the Pulse massacre and Club Q shooting. Panels A, B, and C characterize search intensity for the following search terms: “LGBT,” “shooting,” and “LGBT hate crime.”

F.4.2 New York Times

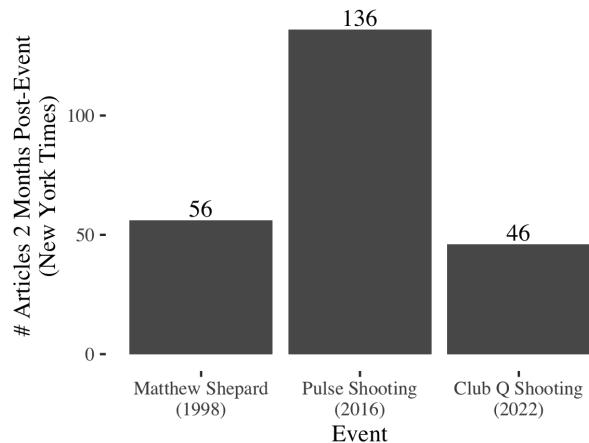

Figure F47: Number of New York Times Articles Related to Matthew Shepard’s Murder, the Pulse Massacre, and the Club Q Shooting In The Two Months After The Event(s). The x-axis is the respective event, the y-axis is the number of articles published in the New York Times in the two months after the incident. Search phrases for the respective incidents are: “matthew shepard AND (murder OR death OR killed),” “pulse AND shooting”, and “club q AND shooting.”

F.5 State-Level Anti-LGBTQ+ Bills Over Time By Partisan Control

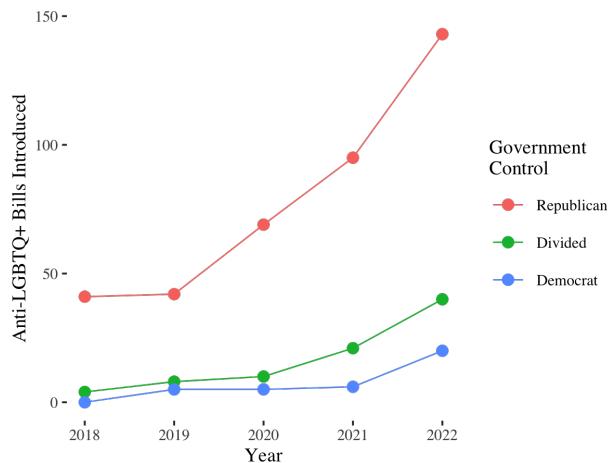

Figure F48: Number of State-Level Anti-LGBTQ+ Bills Introduced Over Time By Partisan Control. X-axis is year, y-axis is the number of anti-LGBTQ+ bills introduced. Color denotes state government partisan control of governorship, upper, and lower house. Data on bill introductions are from the American Civil Liberties Union.

Data on partisan control of state government are from Grumbach (2022). Data on the introduction of anti-LGBTQ+ bills between 2018-2022 are from the American Civil Liberties Union (ACLU).⁴⁷ The data include the following types of bills:

- Anti-Transgender Bills
 - Single-sex facility restrictions
 - First amendment defense actions and religious exemptions
 - Restrictions on identification documents
 - Restrictions on health care/gender-affirming care
 - Restrictions on athletics
- Broader Anti-LGBTQ bills
 - Religious exemption bills
 - Religious freedom restoration acts
 - First amendment defense acts
 - Health care access restrictions
 - Adoption and foster care restrictions
 - Marriage-related exemptions

⁴⁷See <https://www.aclu.org/past-legislation-affecting-lgbt-rights-across-country-2018>, <https://www.aclu.org/past-legislation-affecting-lgbt-rights-across-country-2019>, <https://www.aclu.org/past-legislation-affecting-lgbt-rights-across-country-2020>, <https://www.aclu.org/legislation-affecting-lgbtq-rights-across-country-2021>, and <https://www.aclu.org/legislation-affecting-lgbtq-rights-across-country-2022> for source data.

- Restrictions on schools and student organizations
- Bills preempting local protections

F.6 Anti-LGBTQ+ Right Wing Protests Over Time

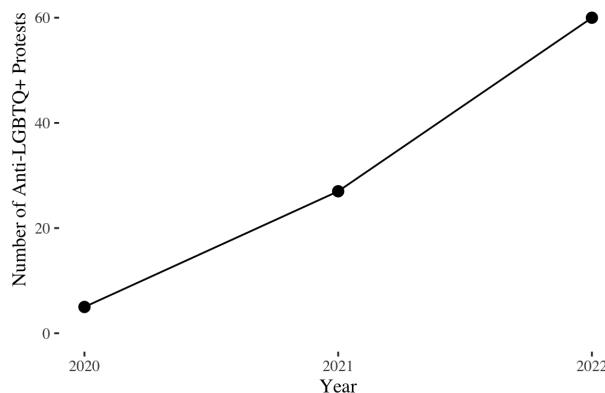

Figure F49: Number of Right-Wing Anti-LGBTQ+ Protests Over Time (2020-2022). X-axis is year, y-axis is the number of anti-LGBTQ+ protests. Data are from ACLED (see: <https://acleddata.com/>, protest keyword = “anti-LGBT”)
